Dr. A. Hewson, of Philadelphia, said that he had tried all forms of antiseptics, but relied now chiefly upon earth or salicylic acid. He believed that dryness was the essential element in any dressing. He never used a ligature, but employed acupressure or torsion. He always used gauze and collodion instead of adhesive plaster, and never allowed water to be used upon a wound during any stage of its treatment. Perfect quietude of the part, infrequent dressings, and the exclusion of any but the actinic rays of light, by a covering of blue paper, all assisted greatly in rapid healing.

Dr. J. H. Pooley, of Columbus, Ohio, said he was very fond of carbolic acid, in the proportion of one to seven of olive oil, freely brushed into a portion of the wound. Under this dressing he had seen wounds in which the time of healing had been reduced from months to weeks. He then spoke of the repressive power which carbolic acid seemed to exert upon granulations after long continuance of application and the necessity for change of dressing. The speaker had had but little experience with salicylic acid, but in one case its application had caused severe pain for an hour.

Dr. Hewson replied, that in the dressing of amputations, etc., salicylic acid gave no pain, but in open wounds it did.

Dr. Wm. Canniff, of Toronto, Canada, said that he fully believed that the air was inhabited by living organisms; but he thought it was still a question whether putrefaction was due to the action of these germs. If Dr. Hodgen's first conclusion was sustained, he submitted that the doctrine urged by Prof. Lister was undermined.

Dr. Hodgen explained that he did not intend to convey the meaning that germs were not present in all cases of putrefaction. The organisms could be introduced in part through the blood.

Dr. Canniff argued that if germs could reach the part through the lungs, etc., it was of no use to exclude them from the wound. He believed that putrefaction could occur without the action of these organisms. The cells of the body had a definite time to live and die, and if, as in a contused wound, these cells had their vitality crushed out of them, they must die. Some would live, others perish, and sequestration was by the process of natural laws. It was asking a great deal to request us to believe that all this was due to air germs, and his own experience refuted it. He then referred to several severe accidents in which, under cold-water dressings, no suppuration had occurred. He believed the results of the Toronto Hospital were as good as any in which the antiseptic system was used. He used antiseptics, not to destroy air-germs, but to arrest putrefactive decomposition due to chemical changes. Cleanliness, rest, and pressure, he considered the essential elements in the treatment of wounds.

Prof. F. H. Hamilton, of New York, referred to the method of treating wounds by leaving them open and exposed, claiming for it an excellent success both as regards rapidity and freedom from suppuration. At St. Francis Hospital, the warm-water treatment had been largely adopted, the part being submerged in the liquid at a temperature of about 95°. To arrest gangrene, 110° was required. The method was an exceedingly simple one, and he claimed that erysipelas, gangrene and pyæmia were almost unknown in their wards.

Dr. J. A. Grant, of Ottawa, Canada, said that although formerly well pleased with cold-water dressings, after a visit to Edinburgh he was thoroughly satisfied that the antiseptic treatment, if properly conducted, would yield better results.

Dr. R. A. Kinloch, of South Carolina, called attention to the importance of absolute rest in the treatment of wounds, and thought that much of the credit claimed by a particular system might be attributed to quietude.

Dr. F. H. Hyde, of Cortland, N. Y., thought that sufficient importance had not been given in this discussion to the fact of the constitutional condition of the patient. Every surgeon knows the same accident or the same operation is followed by far different results. The speaker also testified to the fact that wounds entirely free from dressings did remarkably well.

Dr. J. L. Atlee, of Lancaster, Penn., had lately used chloral hydrate, five grains to the ounce of water, upon several old ulcers. The result was most happy.

Dr. J. T. Carpenter, of Pottsville, Penn., said that in the late war he had treated one hundred cases of hospital gangrene with creasote, and with but two deaths—one from erosion of the artery, the other from thrombosis and heart-clot. This was before the germ-theory was recognized.

Dr. J. Ashhurst, of Philadelphia, thought Dr. Hyde had struck an important point when he emphasized the importance of the constitutional condition of the patient. He was surgeon at two hospitals—the one general, the other for children. In the latter he never lost a case from operation, although the inmates were drawn from the lowest, half-starved class. He attributed this to their freedom from liver, kidney, and other diseases. He believed in constitutional treatment and in good hygiene.

Tuesday September 5th.—Prof. Lister being requested to close the debate, said he had not time to speak fully on the subject, but he would endeavor to answer a few of the objections raised by various persons. First, in regard to the trouble. He thought much of this was occasioned by improper or inefficient apparatus, or unfamiliarity with its use. Any new method, or new operation was a trouble until one has learned the different steps by practical experience. Moreover, he thought it was worth some trouble to be able to dress a wound, an amputation, or an exsection with the absolute certainty that the injury would heal quickly and kindly, without suppuration. Although the operation itself might be accompanied by a little extra amount of inconvenience, yet when the shortening of the treatment was brought from months down to weeks, and the dressings were far less frequent, we should say that the advantage was decidedly in favor of the antiseptic plan.

Another objection made was, that other modes of treatment give good results; but he contended they were not the best results. With strict antiseptic treatment he could cut freely into a joint, or exsect a portion of bone with the feeling of absolute freedom from danger. And then the way the wound behaves. The blood becomes organized under the dressing, and cicatrization takes place without one drop of pus, and almost without granulations, a thing which could not occur save under strict antiseptic dressing. Again, to be able to open a chronic abscess of the spine without fear of fever, pyæmia, etc., requires strict antiseptic treatment. In acute abscesses it is a satisfaction to know that after free incision and pressing out of the pus, not one drop more would appear. In ligation of an artery near a main branch, it is certainly a comfort to feel that no danger is to ensue.

The reporter had raised the point that putrefaction may be due to development of germs from within the body, but every simple fracture disproves this. In every simple fracture there is a severe wound, even if the surgeon does not see it; and if mere feebleness of tissues would lead to putrefaction, it should be seen in every such case.

In chronic abscess, the lining membrane is at first in much the same condition as cicatricial tissue with the epidermis stripped off, and in this condition is far more capable of absorption than afterwards, when it has assumed more of the character of granulations. The greatest danger in opening such an abscess is within the first few days. The speaker said he now used absolute phenol, which was very nearly pure; the solubility and absence of odor were in direct proportion

to the purity of the drug. The pure would dissolve in sixteen parts of water, and in proportion to its solubility is it unirritating. As a detergent, in the proportions of one to twenty, carbolic acid has no equal. Tirsch of Leipsic used salicylic acid, but has returned to carbolic, for purposes of spray.

Prof. L. then showed his atomizer, made by J. Gardener, of Edinburgh. By an arrangement of one tube within another, the vaporization of alcohol is effected, and this being burned produces a rapid boiling of the water, thus securing a large and minutely divided stream of the spray. The flue spray is less irritating to both patient and surgeon, and scarcely moistens even the clothing. The surgeon should always see the spray, so that he may be sure that he is working in it; his hands or instruments should never be outside of this stream of atomized fluid during the whole operation. Should a knife fall without it, it must not be used until again made antiseptic. Everything, sponges, instruments, the operator's hands, skin of patients, etc., must be first soaked with the carbolic solution, 1 to 20. The finger nails even should be cleansed with a brush. Catgut ligatures rendered antiseptic are alone used, both ends being cut off.

In dressing a fresh wound, Prof. L. used a piece of oiled silk covered with a thin layer of copal varnish, in order to protect the surface from the direct effects of the carbolic acid; over this were placed numerous layers of the carbolized gauze, loosely wrapped around; then a layer of Mackintosh cloth, the whole being retained by a bandage of the carbolized gauze, the spray continuing to play upon the part during the entire operation of dressing. No change need be made until the discharge begins to soak through, when the superficial dressing should be removed under spray, but the deeper ones need not be disturbed for weeks. For private practice, a small hand atomizer can be carried about in a box without trouble, and small portions of the dressings removed at a time.

The gauze is simply very coarse open meshed cotton cloth, filled with a preparation of carbolic acid one part, resin five parts, paraffine seven parts; these are melted together, and forced into the cloth under pressure—the apparatus for the Edinburgh Hospital costing only £10. Prof. L. stated that, instead of being an expensive dressing, this gauze, which was capable of being re-carbolized, could be prepared so that the cost in the end would be scarcely more than a penny a yard. A hospital in which the antiseptic treatment was thoroughly used would cost less per bed than one where the ordinary dressings were employed.

The speaker then described the difficulties which he had had with the spray producer, and while he acknowledged that he would gladly dispense with it, he did not see how it could be done. He had also been experimenting diligently to perfect the antiseptic catgut ligature, and he thought he had at last met with success. The material in which he was now preparing his ligatures was a mixture of carbolic acid, glycerin, water, chromic acid, and spirits of wine. In regard to the danger of throwing the spray upon the peritoneum, he had frequently done so in the operation for strangulated hernia, without any evil effects; and Keith, Nussbaum, and others have spoken highly of the antiseptic treatment in the removal of ovarian tumors.

He liked salicylic acid to sprinkle upon wounds on which dressings were to remain for weeks, as the under layers would, when saturated with carbolic acid, sometimes become offensive to the smell, although no putrefaction occurred, nor were organisms to be found. This fetor is due to chemical, not putrefactive changes, and therefore salicylic acid will destroy this odor better than carbolic.

Again, where carbolic acid, long continued, sets up an irritation of the skin, salicylic acid powdered upon it answers an admirable purpose, while it does not interfere with the action of the antiseptic. The speaker then detailed at length his experiments upon the development of germs, and also his many trials in preventing their entrance to certain fluids, as urine, milk, etc.

He was replied to by Dr. T. E. Satterthwaite, of New York. The discussion, which was quite interesting, will be published in the volume of Transactions of the Congress.

TREATMENT OF ANEURISM.

Wednesday, September 6th.—Dr. Van Buren, of New York, Reporter, read a paper on the "Medical and Surgical Treatment of Aneurism."

After a brief word on etiology, and reference to the great value of Holmes' recent lectures on the subject, he spoke of the increasing favor with which medical treatment of aneurism is at present regarded—as Tufnell's method, and of drugs which have been tested, including iodide of potassium. He then discussed the value of carbolized catgut ligature and silver wire, as used by B. Howard; and raised the question whether the Hunterian principle had not been carried to excess by English and American surgeons, and concluded affirmatively as regards larger arteries near the heart. He thought it inapplicable also, to gluteal aneurism, for which he made the original suggestion that the iliac arteries might be effectually compressed by a hand *in recto*, whilst the tumor was being laid open. Distal ligature and compression were illustrated by some recent and interesting American cases, and various forms of compression noticed. In connection with a recent operation on the left subclavian, within the scaleni, Dr. Van Buren discussed the propriety of attempting this operation, and briefly noticed the present attitude of electrolysis, coagulating injections, the introduction of foreign bodies, etc., emphasizing the value of Esmarch's bandage in connection with several of the more modern methods.

Mr. Joliffe Tufnell, of Dublin, said he had brought with him both wet specimens and drawings, which would show what had been accomplished by the system which he advocated. Finding it was not necessary to entirely occlude the vessel, to accomplish a cure, he had placed his patients upon their backs, with good, nutritious diet, which, with reduction of the heart's action, had accomplished several very remarkable cures. In regard to lowering the pulse, a little calculation will show that bringing the pulse down from 86 to 56, will make the total heart-beats 43,000 less per day. For hope of success, the aneurism must be upon the anterior wall of the vessel, the sac must be entire, and there must exist a fibrinating power in the blood.

The gentleman exhibited numerous specimens of cure, and said three months would usually produce this result; but he had caused coagulation in twelve days in a popliteal aneurism. In a limb the member is kept about six inches above the level.

Dr. J. H. Pooley spoke of the advantages of Esmarch's bandage, in rendering feasible the operation of laying open the sac and tying both ends.

Dr. A. C. Post said that the plan last mentioned was hardly applicable to idiopathic aneurisms, although undoubtedly the best in traumatic cases.

Dr. George A. Otis, U.S.A., said the reporter had cited one case of ligation of the subclavian as a solitary example of wound of that vessel in which immediate death had not occurred. This was obviously an error, as several such cases have been recorded by Billroth, and in the Surgical History of the War of the Rebellion, where injuries of this vessel had not proved fatal for several days—in two cases at least, ligation having been performed. The securing of the artery was therefore a justifiable operation.

Dr. J. Ashhurst spoke of the success attending ligation of the femoral in diffusive aneurisms. In these cases he would use Esmarch's bandage, or a tourniquet to guard against hemorrhage.

Dr. S. F. Spier, of Brooklyn, showed an artery constrictor which ruptured the internal and middle coats of the vessel, thus plugging it with its own contents.

Prof. Lister said he had seen a case in Mr. Syme's practice, which had been put to bed for a few days preparatory to ligation of the femoral, for popliteal aneurism. When brought to the operating table the pulsation had ceased, thus beautifully illustrating the value of Tufnell's method. He thought the question should not be, whether the aneurism was idiopathic or traumatic, but rather which was the operation attended with least danger. Ligature of the bronchial would not cure an aneurism at the elbow, be it either traumatic or idiopathic, simply because the anastomosis was so free.

He spoke also of the element of diseased arteries in idiopathic cases, and also as to the varying forms of aneurism, either of which might influence the method of operation. He thought there could be no danger with the abdominal tourniquet, as suggested by Prof. Van Buren, if a sponge was always placed under the pad and slight pressure be accurately made.

In regard to the antiseptic ligature, Prof. Van Buren had claimed that secondary hemorrhage could be avoided by its use, but by far its greatest advantage was due to avoidance of diffuse suppuration. With true antiseptic treatment, he had no fear of bad results, even although a pleural or peritoneal sac were opened.

In naevi the speaker now ligates the base of the tumor with carbolized ligatures, and then injects with hypodermic syringe from one-half to one minim of pure carbolic acid at numerous points. After ten minutes the ligatures are removed and the part simply covered with collodion.

AMBULANCES AND LITTERS.

A paper was then presented on this subject and read by title, translated by Dr. Wm. Ashbridge, of Philadelphia, from the French of Dr. Badoin, Médecin Major 8me Rég't. de Chasseurs à Cheval, France.

TREATMENT OF COXALGIA.

Prof. Lewis A. Sayre, Reporter, then read a paper on this subject, which elicited considerable discussion. The following were the conclusions deduced from it:

1st. Morbus coxarius is a disease peculiar to early childhood, or the age of reckless indifference.

2d. It is almost always of traumatic origin, and not necessarily connected with vitiated constitution.

3d. Rest and freedom from pressure of the parts involved, while at the same time the rest of the body is allowed free exercise in the open air, and a nutritious diet, is the best treatment yet devised.

4th. If this plan of treatment is adopted in the early stages, the majority of cases will recover, with nearly if not perfect motion, and without deformity.

5th. In the advanced second stage, and absorption cannot be produced, then it is better to puncture or aspirate the joint and remove its contents, than to leave it to rupture by ulceration.

6th. In the third stage, and the treatment here recommended has been properly applied without satisfactory improvement, but progressive caries continues, then exsection of the diseased bones is not only justifiable, but absolutely necessary.

7th. The operation of exsection of the hip is easily performed, and attended with no danger.

8th. After exsection of the hip-joint in cases of caries, the recovery is much more rapid and certain, and infinitely more perfect as to form, motion, and the usefulness of the joint and limb, than when left to the slow process of nature's exfoliation.

Thursday, Sept. 7th.—The discussion was opened on Dr. Sayre's paper.

Dr. Post, of New York, thought the reporter spoke strongly when he said the operation of exsection was without danger. All operations of that magnitude were dangerous; yet the ends justified the means in many cases.

Prof. Gross said he could not agree with the reporter's second conclusion. He had thoroughly investigated his cases, and was frequently unable to trace them to any other cause than cold, etc., acting upon a scrofulous constitution. The taint was always present in every case, and the disease could not occur without it.

Dr. W. H. Hingston, of Montreal, stated that he was formerly of the same opinion as the last speaker, but had lately entirely changed his views. He believed in its traumatic origin in almost every case. Dr. Moore, of Rochester, spoke in the same strain. Dr. Campbell, of Georgia, believed it was due to scrofula, as did also Dr. G. Cupples, of Texas.

Dr. T. G. Richardson, of New Orleans, asked, if the disease were of traumatic origin, why did we not have it following luxation of the head of the femur, etc. He said the age of "recklessness" was not the age in which it was most prone to develop.

Mr. Wm. Adams, of London, thought it was traumatic in the majority of cases; and where the injury could not be traced, the constitutional taint would be very marked.

Prof. D. H. Agnew, of Philadelphia, said it did not require a severe blow to constitute traumatism—a simple blow might be all-sufficient to awaken the disease in a vitiated constitution, and every child received such injuries frequently, without knowledge of parents. An accident was the exciting cause in almost every case, but behind this would be found, in the majority of cases, a scrofulous taint.

Dr. Grant, of Ottawa, said he had opened an abscess from coxalgia, and the pus was laudable. He did not believe in its strumous origin.

Dr Gross said laudable pus could never have come from true morbus coxarius. It was always curdy and flaxy.

Dr. Pooley, of Ohio, said if he had had the framing of the conclusion he would have made it even stronger, and would have said coxalgia was never connected with struma, save by accident of occurrence.

Prof. Lister thought, if struma existed at all, it certainly did in coxalgia, a disease corresponding in all its particulars to our idea of that term, *i. e.*, a languid inflammation.

The debate was further continued by Drs. McGuire,

Carpenter, Brodie, and others, after which Prof. Sayre replied to the various objections raised. The reporter's conclusions were voted on, and after considerable alteration, passed. Upon the following day they were referred back to the Section by the Congress, and after discussion were referred to the Committee of Publication, with indorsement of the Section upon all the conclusions except the second, on which the body could not unanimously agree.

EXCISION OF THE INFERIOR MAXILLA.

Dr. J. W. S. Gouley, of New York, Reporter, presented a report of a case of subperiosteal excision of the entire inferior maxillary bone, and solicited from American and foreign surgeons records of their unpublished cases, to add them to those he has already collected for analysis in an essay he is now preparing. The doctor's patient was a female nineteen years old, with phosphorus necrosis of four years' standing, involving the entire lower jaw. She was greatly disfigured by a very large under jaw, made up of an enormous involucrum, rendering mastication impossible. March 19, 1864, the patient having been etherized, the entire jaw was removed by external incision, and she made an excellent recovery. When last seen, seven and a half years after the operation, the bone reproduction extended from the body to the rami of the jaw.

He said it was not common in phosphor-necrosis to find an involucrum, but in his case there was one, while there was none of the pumice-stone deposit of Stanly. He explained this by the violent phlegmonous periostitis which occurred a year previous.

As regards various operations, chiefly modifications of the external incision, he wished particularly to call attention to the intrabuccal, which offers many advantages.

The operation for removal of the lower maxilla was usually accomplished at two or more sittings, but in his list he included as one all which were merely continuations of the same.

Dr. Hutchinson, of Brooklyn, said in malignant tumors he should consider the intrabuccal operation as an unsafe one—there would not be the same certainty of complete removal; but for phosphor-necrosis he considered it perfectly feasible and easy. It was also applicable to removals of the superior maxilla.

Dr. Hyde said the incision must depend largely on the requirements of the case. He had usually removed sequestrum from the inside.

Dr. Gouley, in reply to a question by Mr. Lister, stated that the bone was entirely dead, and should have been removed two years earlier.

Prof. Lister thought the incision should be determined by the tumor. He certainly would not employ the intrabuccal one in malignant cases, but might in innocent ones; although even here in males the scar could be well concealed, and even in females was not serious if made behind the ramus.

CAUSES, ETC., OF CALCULUS.

The paper of Dr. Claudius H. Mastin, of Mobile, Reporter, on "Causes and Geographical Distribution of Calculous Disease," was read but not discussed, owing to the lateness of the hour.

In summing up the *probable* causes of calculous affections, he considered: Hereditary influences, digestive trouble, sedentary life, indulgence in stimulating food, climatic changes, deficiency of clothing for proper protection of the body, an arrest of the healthy function of the dermoid tissue, want of harmony between the secreting and excreting organs, catarrhal affections of the uropoëtic viscera, injuries of the spinal cord, foreign bodies in the bladder producing cystitis, and the geographical distribution of calculous affections in North America.

SUBCUTANEOUS DIVISION OF THE NECK OF THE FEMUR.

Mr. William Adams, President of the Medical Society of London, then read a paper on this subject.

In it he had collected all the published cases in which this had been performed—twenty-three in number (five by himself)—and from the good results already attained, he should be prompted to do it in well-selected cases when the deformity is inconvenient, as there had been but one death, and that in an unfavorable case. He spoke of the malpositions in which anchylosis might occur, and showed the necessity of careful watching during the treatment of all hip diseases or injuries. The straight position in one case prevented the patient sitting on a chair, and also debarred her from emptying the rectum save while standing. Other serious malpositions were referred to. Numerous photographs were exhibited in illustration. The operation is very simple, the soft tissues being pierced down to the bone, the periosteum divided or scraped away, and the saw carried down along the blade of the knife, it being carefully noted that in sawing, the cut should be made at right angles with the longitudinal axis of the neck. The saw is blunt-pointed, very robust in the handle, and with cutting edge just as long as the diameter of the bone, that no damage be done to surrounding tissue. About two or three minutes usually severs the bone. When the head and neck have disappeared, the section may be made through the trochanter minor. Extension is applied by weight and pulley, and passive motion instituted at the end of first week.

His conclusions were: 1. That bones can be divided subcutaneously, the same as tendons. The operation is a well-established one, and the cases almost uniformly do well. 2. Long bones can be divided subcutaneously at any point with little risk. 3. In a large number of cases the operation is followed by but little irritation, and there is seldom pain or suppuration. 4. In some there is slight suppuration, but not serious, and in one case there was death from pyæmia. 5. The operation usually corrects the deformity, though anchylosis in the more favorable position may occur. In some cases motion has remained for a time, and in one case as long as three years.

Friday, September 8th.—Dr. A. C. Post related a fatal case in which gangrene set in; found subsequently to be due to the femoral artery and vein being hooked on the stub end of the bone. Subcutaneous division of the neck within the capsule would avoid this and other dangers.

Dr. Quimby, of New Jersey, asked Mr. Adams whether any classification had been made by him as to the causes of anchylosis.

Mr. Adams replied that about half were the results of coxalgia, the other half pyæmic, rheumatic, or traumatic. He always avoided scrofulous cases if possible, as they often did poorly.

Dr. Servais, of Belgium, advocated fracture of the bone by brute force, under the view that the weakened point was just below the trochanter minor, and it would first give way at this position, the point selected by Mr. Adams in cases where the head and neck had been destroyed. The advantage claimed was, that only simple fracture remained to be treated.

Mr. Adams replied that though he had several times broken femurs accidentally, he feared direct force would not be reliable as to the exact position.

Dr. McGuigin, of Iowa, claimed to have successfully performed subcutaneous section of the neck of the femur with the chain-saw, twenty years ago.

Prof. Joseph Pancoast, of Philadelphia, stated that Dr. Rhea Barton did not remove a triangular piece, as reported; he simply sawed through the bone.

Prof. Sayre spoke of two cases he had already reported, and said he was decidedly in favor of Mr. Adams' plan, and should hereafter adopt it when feasible, as it was far more simple. He suggested that extension be made after the operation at once—not waiting, as Mr. Adams had said, for three or four days. Mr. Adams' report confirmed his previous suspicions that anchylosis was likely to occur subsequently, though Dr. Post had a case in which good motion was secured. He then raised the question of the extensibility of muscles, but did not think this should prevent immediate extension.

Dr. Richardson, of New Orleans, related a case in which he accidentally broke the neck of the humerus in attempting to reduce an old luxation. He placed the broken end in the axilla, and secured a good movable joint.

Dr. Moore, of Rochester, called attention to the experiments of Bly, of that city, on muscles of animals, who had found them capable of slight extension.

Mr. Adams said it had been his intention in the future to apply extension immediately, and to enforce passive motion under chloroform every week.

Prof. Pancoast favored the subcutaneous boring and fracture of the bone.

Prof. Lister said in two cases after exsection of the neck of the femur he had applied too great extension, and prevented union.

WOUNDS OF THE ABDOMEN.

Prof. L. A. Dugas, of Georgia, then read a paper on "Penetrating Wounds of the Abdomen."

He said that penetrating wounds have hitherto been considered very fatal, and peritonitis assigned as the cause, and all treatment directed to it. Fatal termination usually takes place in twenty-four to forty-eight or sixty hours at most, but no process of inflammation with which we are acquainted proves fatal in that short time. He thinks fatal result is due to septicæmia, and not to inflammation, and treatment should be directed to prevent that, by laying open the abdomen, cleaning surfaces, stitching wounds of intestines, if any, ligating vessels, etc. By laying open abdomen early, we can examine and detect lesions of intestines or vessels; the wound cleansed can thus be reduced to its simplest expression.

Dr. Moore, of Rochester, said death not unfrequently occurred in twenty-four hours, with unmistakable evidences of peritonitis.

Dr. Campbell, of Georgia, heartily agreed with the writer's conclusions, and believed it would be much better in cases of concealed hemorrhage to lay open the abdomen, search for the bleeding vessel, wipe out blood clots, and close tightly.

Prof. Lister remarked that the experience of ovariotomists proves that even a cut at the linea alba is devoid of danger.

Dr. Post said that the paper was an excellent one, but he did not think it safe for the Section to adopt the conclusions without more discussion than the limited time permitted. It was therefore referred to the Publication Committee.

OPENING THE SAC IN HERNIOTOMY.

Dr. Fred. Hyde, of Cortland Village, N. Y., read a paper on this subject.

After giving a résumé of the usual methods of herniotomy, he said division of the sac is often necessary. Experience in Petit's, or the minor operation, proves that the cases which are most successful are those which furnish most favorable results with division of the sac. He said the objection that it exposes to peritonitis is refuted in the greater danger of returning the contents of the sac, with their average morbid state, into the abdomen. The objection that opening the sac exposes to air, light, temperature, etc., is no weightier than in ovariotomy and other abdominal operations. Other reasons were cited by the writer as to its safety, etc.

Prof. Joseph Pancoast remarked that the procedure, though undoubtedly proper in many cases, is very frequently unnecessary. In several cases of old large herniæ he had divided the strictures by a simple subcutaneous incision of the constricting point.

Dr. Post said the views of the essayist, if followed out to analogous conclusions, would tend to prove that Cæsarian section was preferable to a normal delivery. In some cases the sac should undoubtedly be opened, but in others there was no more reason for doing this than in refusing to attempt taxis for fear of some already existing lesion of the bowel.

ANÆSTHESIA.

Dr. Addinell Hewson, of Philadelphia, read a paper on "Anæsthesia, as produced by Nitrous Oxide and Rapid Breathing."

He stated the method had been suggested to him by W. G. Bonwill, a dentist of Philadelphia, and he had tried it in a number of cases, in public and private practice, with varying but satisfactory results. The method pursued was to cause the patient to breathe from forty to fifty times in the minute, the effect of which in from three to five minutes was a tingling of the surface, with flush face. Consciousness remained unimpaired, and the patient would perform any act desired, but was rendered totally devoid of sensibility. This method would be advantageous for short minor operations, especially those about the nose, throat, etc. The process occupied a longer time in young people and in cold weather. He explained the theory of its action by the retention in the blood of carbonic acid.

Owing to the closing of the Congress, this paper was referred to the Publication Committee, without discussion, as were also the two essays of Dr. H. F. Campbell, of Georgia, on "Urinary Calculi: Their Etiology Explained by the Neurodynamic Theory," and "The Ligation of Arteries for the Arrest of Inflammation and Prevention of Gangrene," and also Dr. E. M. Moore's paper on "Fracture of the Clavicle."

(*To be continued in our next.*)

Bordeaux Medical Prizes.—The Medical and Surgical Society of Bordeaux offers a prize of 1,000 francs, to be awarded at the end of 1879, for an essay on "The microscopical study of the human blood, fresh and dry, in the fœtus and in the adult, compared with that of other mammalia, in a medico-legal point of view." The essays are to be written in French or in Latin, and sent to M. Donaud, Secretary of the Society, before August 31, 1879.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Sept. 10th to Sept. 16th, 1876.

FORWOOD, W. H., Surgeon. Relieved from duty in Dept. of Texas, and to report by letter to the Surgeon General when able to resume duty. S. O. 188, A. G. O., Sept. 11, '76.

JAQUETT, G. P., Asst. Surgeon. At expiration of his present leave of absence to report in person to the Comd'g General Dept. of the South for assignment. S. O. 188, C. S., A. G. O.

BROWN, J. M., Asst. Surgeon. Relieved from duty in Div. of the Atlantic, and to report in person to the Comd'g General Dept. of the Missouri for assignment. S. O. 188, C. S., A. G. O.

TAYLOR, M. K., Asst. Surgeon. Ordered before the Army Medical Board, New York City, for examination, for promotion, and on completion thereof, to rejoin his proper station. S. O. 188, C. S., A. G. O.

O'REILLY, R. M, Asst. Surgeon. Granted leave of absence for twenty days. S. O. 182, Div. of the Atlantic, Sept. 13, '76.

APPEL, D. M., Asst. Surgeon. When relieved by Asst. Surgeon Perley at Fort Monroe, to report in person to the Comd'g General Dept. of the Missouri for assignment. S. O. 188, C. S., A. G. O.

CUNINGHAM, Thos. A., Asst. Surgeon. Assigned to duty at Fort Rice, D. T. S. O. 112, Dept. of Dakota, Sept. 12, '76.

PERLEY, H. O., Asst. Surgeon. (Recently appointed.) To report in person to the Comd'g officer, Fort Monroe, Va., for temporary duty at that post. S. O. 188, C. S., A. G. O.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending September 16, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Sept. 9.....	2	19	8	3	2	22	1
Sept. 16.....	0	25	12	2	2	31	0

Two cases of yellow fever occurred, both from Savannah.

LAW FOR POISONS.—A new law is about to be made in England relating to the sale of poisons.

MEDICINE UNDER ROYAL PATRONAGE.—The King of the Belgians has placed a palace at the disposal of the Academy of Medicine in Brussels.

PAVILION HOSPITAL IN PARIS.—A new hospital on the plan of isolated pavilions, to contain three hundred beds, is being built in Paris.

HYDROPHOBIA.—Two deaths from this disease have been reported in Scotland. In one case the period of incubation was fifteen days, in the other two months.

OBESITY TREATED BY SEA-WATER.—A writer in the *Paris Médicale* recommends the treatment of obesity by the administration of sea-water, and the consequent residence by the seaside. The dose prescribed is a small glassful three times a day in a little fresh water or milk. Sea-baths are also recommended. We should think that the drinking and bathing might be advantageously combined to save time. In that way the dose, especially in surf-bathing, could be taken "plain," although the quantity could not, for obvious reasons, be regulated with exactness.

HOW TO MAKE LEECHES BITE.—A Mr. James P. Myles, of Parsonstown (*Dub. Med. Press and Circ.*), has always made leeches bite by placing them in an apple properly hollowed out, and applying them over the part.

PLUCKING LIVE POULTRY.—The English Society for the Prevention of Cruelty to Animals has announced the intention of prosecuting all persons detected in plucking the feathers from live poultry.

SWIMMER'S CRAMP.—The loss of body heat in water is now held to be intimately associated with the cramp which so often seizes even able swimmers. Here there is not only a general powerlessness induced, but the spasm of the muscles connected with respiration diminishes the capacity of the thorax, and the cramp-stricken swimmer often disappears immediately without warning, never to appear alive. The buoyancy conferred by the chest being full of air, is largely reduced by this diminished thoracic space, and the body at once goes under water. No skill in the art of swimming will secure any one from this risk, and when the water is cool it is well that the swimmers keep near shore, or at least near each other, so that aid can be readily rendered if required.—*Sanitary Record.*

A SIMPLE DISINFECTING APPARATUS.—Mr. Charles Gander, an English sanitary inspector, thus describes a simple disinfecting apparatus which he has devised: "I have the sulphur melted in an iron pot over the fire in an outhouse, and have some tin moulds prepared about three inches in diameter, and two inches deep. Place a ball of deal shavings as large as an egg in the mould, and pour about one pound of the sulphur over it. When cold or set take them out of the mould. These balls are then ready to be burned in appropriate vessels at a moment's notice."

BRITISH ARMY MEDICAL SERVICE.—At the recent examination there were fifty-four candidates for seventy-seven vacancies. Fifty passed the examination. What a good chance the remaining four would have had if they had been even decently prepared.

THE FIRST ANNUAL MEETING OF THE AMERICAN GYNECOLOGICAL SOCIETY was held at the New York Academy of Medicine, Sept. 13th, 14th, and 15th, 1876.

At the close of the morning session on Tuesday, the members and invited guests repaired to the residence of Dr. E. R. Peaslee, where a sumptuous lunch was served.

On Wednesday evening the President, Dr. Fordyce Barker, gave a reception at his residence, 85 Madison Avenue, where a most agreeable hour of social entertainment was spent.

On Thursday the members and invited guests partook of a munificent collation at the residence of Dr. T. Gaillard Thomas, and on Friday a bounteous repast was provided at the residence of Dr. T. Addis Emmet. How the doctors *discussed* things at those gatherings!

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

SPECIALISM AND GENERAL PRACTICE.

It is so seldom that any writer takes the pains to plead the claims of the general practitioner against those of the now so fashionable specialist, that Dr. M. H. Henry deserves the thanks, not only of the audience which listened to his alumni oration,* but of the unseen multitude of his professional brethren which is reached through the pages of the press. His bold attack on the abuses in medical education and medical practice will meet a responsive sentiment in the heart of every honest and conscientious worker in our ranks. Although the view taken, that no man can be a specialist "until he has won distinction by ripe clinical observation, a good knowledge of pathology, histology, and microscopy," is not by any means an original one, it is, nevertheless, so well enforced in his remarks on the occasion alluded to, that it leaves little else to be said.

It is now so much the fashion to manufacture specialists to order that it is time that some manly attempts were made in the direction of reform. We have on former occasions repeatedly alluded to the evils connected with such a pernicious system, and are glad of another opportunity of bringing it to the serious consideration of our readers.

Specialism, in the mind of the medical student, is always associated with pecuniary success. Naturally he is inclined to tack his capabilities to some particular organ of the body as soon as he possibly can. Consequently when he graduates in medicine he commences the special study at once. In order, however, that there may be some tangible reason why he should be entitled to take his new departure, why he should seem to have more than the usual opportunities for fitting himself for his specialty, he seizes the convenient pretext of "brushing up" abroad, and being an attaché to some foreign clinic. In the course of a few months, during which an occasional article from his pen appears in the medical journals, he comes home ladened with all the glittering armory of his assumed rank. Next, if he have friends, he is appointed as summer lecturer to some of the medical colleges, and at once appears as an authority in his chosen branch; is careful to speak in "open meeting" at every opportunity, and advertise himself as a specialist on the slightest provocation. No discussion bearing even remotely on his branch is considered complete without his opinion or his suggestion, and it becomes generally known that he must carry his pack wherever he goes. These are what may be called pseudo-specialists, and we are sorry to say that they are becoming quite numerous.

For pure specialism—that is, the study of a class of diseases as a natural outgrowth of general practice—we have the highest respect. Such special studies are more the result of accident than of preconceived notions or of pecuniary expediency, and are always attended with brilliant results. A medical man who becomes thoroughly grounded in the general practice of medicine, with a natural leaning to a particular branch, becomes a specialist almost imperceptibly to himself. It becomes a natural outgrowth of opportunities, tastes, and circumstances, and gives himself the broadest possible foundation for a reputation.

Dr. Henry very truly says that the greatest specialists have always been the best general practitioners. Such specialists are so far from being one-idea men that they are capable of concentrating a cultivated knowledge of the general diseases upon a favorite branch, grafting, so to speak, their favorite study upon a full grown and thrifty tree. This is legitimate specialism, which will always thrive in spite of itself, and will always bear good fruit. To this method of studying special diseases, by men specially adapted to it, general medicine owes its present advanced stride towards an exact science and its wonderful achievements in curative measures. But alas! how few of such specialists we have among us, compared with what we might have if the circumstances attending the manufacture of the fashionable "ologist" were different.

The necessity for a general knowledge in medicine in the successful pursuit is well illustrated by Dr. Henry. One of the striking examples which he relates is the following:

"Again, a gentleman, who had been for a long time under the care of a great experimental physiologist (who devoted himself to nervous diseases), asked me to give him a letter of introduction to an oculist. He mentioned that his physician was treating him for softening of the brain—he was then absent from the city—and, as his vision was becoming impaired, he desired to consult an oculist. I gave him a letter of introduction to an ophthalmologist of deservedly great repute—one who is highly cultivated in the general science and art of medicine, and its literature.

* Specialists and Specialities in Medicine. An Address before the Alumni Association, University of Vermont, June 27, 1876, by M. H. Henry, M.A., M.D.

An examination with the ophthalmoscope displayed beyond any doubt that the so-called softening of the brain was—Bright's disease in an advanced stage. The attention of the pure 'nerve doctor' was subsequently called to the case, and he gracefully admitted his error. Now, was such an error of diagnosis pardonable in one who claims a very exalted position, and who charges correspondingly large fees for his valuable services! A few years judiciously spent in the practice of general medicine would enable any one of average intelligence to differentiate between a case of softening of the brain and Bright's disease."

The difference between the natural and manufactured specialist is no less striking in connection with success in practice. With the former, success, far from being a consequence of special practice, is a cause for it, while with the other the rule is a hard and desperate struggle for notoriety and money. As a consequence of this latter, cliquism is engendered, and every means taken by his friends to hold up the hands of their weaker brethren. This cliquism has, in many cases, so completely encircled itself around the faculties of our colleges, that no one not in the ring can hope for patronage or recommendation. If a would-be specialist is fortunate enough to get a position as lecturer, or better still as professor, it becomes a matter of principle with all connected with the school to help him. These men succeed after a while, but it is not because they are well-qualified specialists.

Previous general training has no small advantage in the development of taste for given special studies. There is often danger that a young man may choose the wrong specialty, and bring himself to grief by the necessity to atone for his precipitancy. We have known of some who have started out to be ophthalmologists and ended in being lithotomists; some who have commenced as laryngologists and ended as dermatologists; some who have begun as physiologists and ended as obstetricians; while others have tried every specialty, and in the end make the best general practitioners. Dr. Henry has done a good service to his brethren in exposing the abuses connected with the practice of medicine, and especially with pseudo-specialism and its attendant professional quackery. Referring to some of these, he says:

"I think that I may fairly claim that the wane of public confidence in the regular practitioner—a fact beyond doubt or dispute—may justly be attributed to the subdivision of labor, and the want of unity and harmony in practice. Experience has forced me to believe that the evils of this subdivision are individually nursed and fostered through lack of proper general qualifications, indolence, and the greater prospect of large fees. Diseases that were skilfully and successfully treated, in the early part of this century, by the general practitioner, are now sent from one 'ologist' to another, until the sufferer, exhausted of patience and means, seeks, in utter despair, the assistance of the nearest quack. It is useless to deny the success attending, at times, the efforts of these impostors. Many of them are wise in the ways and *personnel* of the world. They listen attentively to the course of treatment that has been pursued, and they discover previous excessive and meddlesome interference as the cause of the failures. May not some of the successes claimed by the followers of the mock science of homœopathy (in cases that have previously been under the care of so-called better educated practitioners) be attributed to this cause, and a nice appreciation of what *not* to do under certain circumstances?"

OUR REPORT OF THE INTERNATIONAL MEDICAL CONGRESS.

We have devoted a considerable amount of space in the present and two preceding numbers to a report of the International Medical Congress. It is to be hoped that our estimate of its value to our readers is commensurate with the time and labor which have been expended upon it in regard to detail and accuracy. The abstracts of the papers have been made with the greatest care, and the discussions have been elaborated to the utmost extent of allowable space. The great variety of the subjects treated, and reputation of the authors, give to the reports a value which is quite unique. We venture to say that never before in the medical history of this country has a more distinguished number of physicians and surgeons been assembled to treat upon topics in which they were so directly interested, and in which they are considered to be experts. While we take occasion to thank all those gentlemen who have so kindly aided us in the making of our report, we cannot refrain from again referring to the stupid resolution of the Congress which might have prevented any part of the proceedings from appearing for a long time to come. Our course in presenting this report, despite the resolution of the Congress, is in vindication of what we consider to be the right of any medical journal to give the proceedings of any public medical meeting it chooses, without restriction.

Unhealthy Homes.—A writer in the *Christian Union* details some interesting personal experiences referring to bad drainage in three houses, which were in turn occupied by his family. In the first a drain communicating with a cesspool, ran directly under the furnace, the foul gases by means of the latter finding their way into every room. In the second there was practically no drain at all; the rooms were constantly damp, and the level of the well was not unfrequently above that of the cellar bottom. In a third, on certain occasions, the well, cistern, and cesspool were indirectly and yet very effectively made to communicate with each other. But after all, this is the old story.

Reports of Societies.

INTERNATIONAL MEDICAL CONGRESS.

SECTION OF OBSTETRICS.

Monday, September 4th, 1876.—Dr. Robert Barnes, of London, chairman, was introduced by Prof. Wm. Goodell. He paid a graceful tribute to the American medical profession, and to American gynæcologists, who had done so much towards making obstetrics an exact science.

NON-PUERPERAL HEMORRHAGES.

A paper on "The Causes and Treatment of Non-puerperal Hemorrhages of the Womb" was read by Prof. Wm. H. Byford, of Chicago, Reporter, ordered to be published, and a vote of thanks tendered the author.

He described the uterus as naturally a hemorrhagic organ; the menstrual changes depending on the ovarian reflex nervous influence exerted unremittingly through the genito-spinal centre. These changes consist of hypertrophy at the commencement of the menstrual flow, denudation of the mucous membrane, and the involutions of that period. He referred at length to the various constitutional and local causes producing disturbances of harmony and profuse flow as a result, and afterwards described the treatment, which is curative, removing the pathological conditions; palliative, such as will stay the bleeding until radical treatment can have its effect.

Prof. Goodell called attention to the inertness, in these cases, of pure astringents, with one exception, when administered by the mouth. He thought the chief good from the use of acetate of lead was through the opium that generally accompanied it. The exception is gallic acid, which he had found very effective (grs. xx.–xxx. every hour). He had given as much as half an ounce through the day (in treacle or jelly). In a few cases ergot increased the bleeding in some unaccountable way, but in most instances it proved valuable, especially hypodermically. Free dilatation of the cervix is often sufficient to check bleeding; after removing the sponge-tent he applies chemically pure nitric acid by a swab to the whole interior surface of the womb, with excellent results. He endorsed Prof. Byford's recommendation of bichloride of mercury in the general treatment, and thought the result was not wholly due to its alterative effect, but largely to its power, in small doses, of increasing the number of red corpuscles, thus correcting the anæmia generally present. During hemorrhage he applies heat to the dorso-lumbar region, and gives internally cinnamon tea, or cinnamon boiled in milk, on purely empirical grounds.

Dr. J. W. Rosebrugh, of Hamilton, Canada, thought Professor Goodell had failed with the acetate because his doses were too small. Dr. Workman, of Toronto, gives it in post-partum hemorrhage in doses of a half to two drachms, and claims that he can relieve any such case by two or three doses. It is a valuable remedy in an emergency.

Dr. Edward M. Hodder, of Toronto, thought the discussion should be restricted to non-puerperal hemorrhages. He uses internally tr. cinnamon. acid. sulphuric, and tr. cimicifuga, with local applications of dilute Monsel's solution by means of a glass tube directly to the uterine interior.

Prof. Alex. R. Simpson, of Edinburgh, considered the uterus as "uncertain, coy, and hard to treat;" no treatment would suit all cases. Oxide of zinc he had found to materially reduce the menorrhagia (gr. i. thrice daily, or gr. ss. oftener). The latter may return from force of habit after the uterus is restored to a healthy condition, especially in hyperæmic cases. He has no great faith in the vaginal tampon as a direct preventive of uterine hemorrhage, but it is sometimes beneficial by the impression and confidence it gives the patient. The sponge-tent is preferred generally, as it opens the way for subsequent exploration and treatment. Nitric acid may be applied in the intervals, but in actual hemorrhage he prefers the perchloride or persulphate of iron. In obscure cases and where the mucous membrane is granular, Prof. James Y. Simpson's plan of scraping off the mucous membrane with a curette proves effective; he had seen cases cured by it without astringents.

Dr. Thos. W. Gordon, of Ohio, recommended bringing up the system and full doses of quinia.

Dr. H. F. Campbell, of Georgia, had noticed a periodical character in the bleeding in malarial regions, and uses full doses of quinia. The uterus being engorged from malposition, he insists upon its nightly self-replacement by the patient as indispensable. He uses large cold-water injections between the menstrual periods, with good results.

Dr. Thos. F. Rochester, of Buffalo, thought quinia had an ectrotic influence apart from its anti-periodic power, being valuable in regions non-malarial.

Dr. B. F. Sherman, of New York, recommended Sims's styptic cotton for a tampon, and in granulations a saturated solution of permanganate of pota-sa. In obscure cases he gives internally oxide of zinc with opium (gr. i. to gr. ½).

Dr. Chas. Shepard, of Michigan, had checked hemorrhage by injecting ice-water through a female catheter into an india-rubber bag or condom, which, having been previously carried up through the cervix, applied itself closely to the uterine interior.

Dr. Rosebrugh thought gallic acid the only reliable astringent internally. Locally, Monsel's solution is applied *guttatim*, through a glass tube converted into a syringe, by placing a rubber ball at its end.

Dr. Robt. Burns, of Philadelphia, gives tonics, and applies locally a solution of a drachm each of tannic acid and sulphate of zinc in an ounce of glycerine, with excellent results.

Prof. Theoph. Parvin referred with commendation to Trousseau's plan of injecting quantities of hot water, and applying heat to the spine. Hemorrhage, generally accompanying endometritis, can be relieved by scraping or pinching off portions of mucous membrane with forceps, and applying Churchill's tr. of iodine.

The Chairman referred to the mutual advantages of meetings of this kind, where men met to express and compare their views of disease and methods of treatment, and profit by each other's experience. To review remedies and expedients recommended, he would say, first, that quinine was very valuable in the treatment of metrorrhagia, especially with sub-involution. He had noticed the law of habit mentioned by Prof. Simpson, in hemorrhages where the uterus was healthy, occurring independently of ovulation and often post-climacteric. They were to be attributed largely to regional attraction of blood to the uterus. Attention must be paid to the constitutional state, especially where no local lesion can be detected. Topically, the most efficacious plan is to dilate the cervix and inject astringents. Gallic acid had succeeded in his hands given by the mouth; but remedies not strictly astrin-

gents are useful, such as digitalis, reducing the heart's action and sometimes checking the bleeding. He had also good results from witch-hazel. The curette treatment should not be adopted in malignant disease, as it may be followed by furious bleeding. It should be handled with great care.

Prof. Byford said that in the vast majority of cases, hemorrhage from a non-pregnant uterus is due to one of two conditions: 1. Hyperemia. The treatment should aim at condensation of uterine structures; here quinia is second only to ergot. Sponge-tent also induces condensation by pressure. 2. Vitiated state of mucous membrane from inflammation or growths, this structure giving way more readily under the menstrual molimen and bleeding more freely; topical applications are indispensable. He had also noticed a periodic character in metrorrhagia in malarial districts. Where bleeding occurs after menopause from determination of blood to the womb, better results had been obtained by him from large doses of quinia and iron than from ergot. The tampon when used should not simply be placed against the os, but packed in front and behind to compress the cervix; he had never witnessed any bad results from its use.

LABOR IN NARROW PELVES.

Tuesday, September 5th.—Dr. Barnes in the chair. Prof. Wm. Goodell, Reporter, read his paper on "The Mechanism of Natural *v.* Artificial Labor in Narrow Pelves."

After defining a narrow pelvis, and describing the more common kinds of pelvic deformity, the following topics, regarding alone the mechanism of labor, were introduced for discussion by Dr. Goodell: The mode in which the head enters and passes the brim in the flat pelvis; and also in the generally contracted pelvis, the commonly accepted doctrine of the initial flexion of the head being contested; the manner in which the after-coming head behaves in the flat pelvis; and also in the generally contracted pelvis; the effect instrumental interference has on the mechanism of labor in such pelves; the inquiry whether turning has any mechanical advantages over the use of the forceps; with the following general conclusions deduced from a consideration of these questions, the scope of the paper being strictly limited to the mechanism of labor in narrow pelves:

1st. The unaided first-coming head and aided after-coming head observe in a flat pelvis precisely the same general laws of engagement and of descent. Hence, version here means art *plus* nature.

2d. The forceps, however applied in a flat pelvis, antagonizes more or less with the natural mechanism of labor. Hence, the forceps here means art *versus* nature.

3d. The aided and unaided first-coming head observe in a uniformly narrowed pelvis precisely the same laws of engagement and of descent. Version violates these laws. Hence, the forceps here means art *plus* nature; version, art *versus* nature.

4th. At or above the brim of a flat pelvis, fronto-mastoid or even fronto-occipital application of forceps interferes less with the moulding of the head, and violates natural mechanism of labor less than biparietal application.

5th. In flat pelvis, the vectis aids natural mechanism of labor, and therefore meets applications better than the forceps.

The Chairman pronounced this to be the most able summary of the matter yet heard by him. The passage of the fœtus through the pelvis, and the obstructions to its progress from deformities, were not only to be studied from experience, but, as the conditions are mechanical, by *à priori* reasoning, though experience must be the test.

Prof. Byford had heretofore recommended the use of the vectis in the fore- or after-coming head when above the brim, and applying the forceps in the canal; but, after hearing this able paper, will be inclined to turn in kidney-shaped pelves, instead of delivering directly.

Prof. Wm. T. Lusk, of New York, does not believe, as stated in the paper, that the forceps tend to produce extension of the head, but that they will bring it down just as they find it at the pelvic brim. He applies the forceps, pulls the head beyond the constriction, then takes them off, allows the patient to come out of the anæsthesia, and reapplies them in the canal. The danger of applying them above the brim is exaggerated, but it would be wrong to pull the head directly down without reapplying them.

Prof. Goodell, in reply to a question from Dr. Squire, of Elmira, whether his remarks applied also to the forceps of Chassaignac, said he had no experience in their use. It was significant that the French are tending in this direction of mechanical aids to delivery by bands, straps, and pulleys, borrowing expedients from the veterinary surgeon. In France, turning is so rarely performed as to be almost unknown. Drs. Blot and Pajot, of Paris, who practice turning in emergencies, are the only ones, as far as he knows, who oppose the use of these agents in their practice.

Prof. Simpson said that the flat pelvis presents peculiar advantages for version being performed here with the best hope of success, and theoretically the best result would be anticipated from bringing the base of the skull to the pelvic brim. He thought the amount of force applied to deliver the head after version might endanger the neck of the fœtus, and cited Boudin's experiments on the comparative force required in using forceps and by dragging after turning, the forceps being deemed better in uniformly contracted pelves from their compression of the frontal bones. He had himself found it impossible to apply forceps to the sides of the head when above the brim. They can be applied to the occiput and sinciput, and when the head comes into the canal, removed and applied to the sides.

The Chairman had practised version instead of the forceps where contraction was at all marked. In minor degrees of contraction, forceps aid in elongating the head and assist delivery. The frequency of occipito-posterior positions in contracted pelves enforces Dr. Goodell's arguments. He cited a case of difficulty at the brim, attended by him in five successive labors, the position in all being occipito-posterior. Another case had some contraction; the first child was delivered by forceps dead; in the succeeding two labors, version being resorted to, the children were born alive.

The vectis might be used in minor degrees of contraction where forceps would do as well or nearly as well, but between the forceps and version the vectis does not come in. In version the great danger to the child is in the amount of traction employed. This risk may be reduced by pulling in the line of axis of the superior strait, so that the head may rotate around the projecting promontory as a centre, and by having an assistant push the head backwards with his hand in the hypogastric region. He has seen a child's head pulled off by injudicious traction. Pull the body downwards and backwards until the head has rotated around the promontory, when the forceps may be applied and delivery completed in the line of Carus's

curve. The use of forceps in the fore-coming head is not based on sound mechanical principles in contracted pelves, except in minor degrees of deformity. When ordinary delivery is impossible, with no hope of saving the child, perforation of the head and escape of a few ounces of brain matter allows the skull to collapse, and delivery is comparatively easy.

Prof. Goodell said that he had been staggered by Boudin's experiments until he found the error in them. A pelvis was used with a movable promontory made to project by a screw. The pelvis itself was not a normal one, and every turn of the screw converted it more and more into a uniformly contracted pelvis, and not into the flat pelvis. Again the traction was straight; being made of pulleys attached to the wall, it allowed of no rotation. In kidney-shaped pelvis the promontory is rounded; in these experiments it was sharp. In reply to Prof. Lusk, he said the forceps were of advantage in many cases not mentioned, but he had confined himself to the conditions named in the paper.

RELATIONS OF CONVULSIONS TO HIGH TEMPERATURE.

A paper was read "On the Management of Convulsions in Children, depending upon a High Temperature of the Body," by T. K. Holmes, M.D., of Chatham, Ontario, Canada.

The writer sketched the various causes of eclampsia in children, and believed that in many cases the convulsions are directly attributable to the effect of high temperature on the nervous system. The following propositions have been confirmed by experience: that extreme nervous susceptibility of children under ten years of age, predisposes them to convulsions; that bodily temperature of 103° (F.), and over, tends to produce them; that their severity bears a direct ratio to intensity of fever; that they are most apt to occur at the onset of the morbid attacks; and that whatever reduces temperature arrests or modifies the muscular spasms.

He referred to the indications for treatment in these cases, as suggested by the propositions just given, and stated that these can be accomplished more readily and safely by external than by internal medication—heat which exhausts the power of the heart, or remedies which weaken cardiac power, being generally inadmissible. The bath being a thoroughly efficient substitute, should be resorted to in such cases. Several cases treated by the author were mentioned to show that in simple pyrexia, without zymotic influence, convulsions were caused by heat and promptly controlled by the bath. Tepid water is at first used to prevent alarm or shock, gradually reduced by adding ice water to about 60°, and until the axillary temperature becomes nearly normal, the patient being then taken out and put in blankets. The temperature of the body is not to be reduced in the bath to below the standard of health. This treatment is also available in diseases attended by high temperature, without convulsions. Other indications require treatment in convulsions, as the bowels, etc.

The Chairman said the rise in temperature was due in these cases to nervous irritation or blood poison. It would be interesting to know whether blood poison or hot blood, acting on nerve-centres, produced convulsions; but with rise of temperature there is unquestionably increasing liability to eclampsia. In some cases convulsions occur without material elevation of temperature, as in uræmic convulsions after scarlatina. He thought that scarlatinal patients could be dipped into the cold bath. He had for a long time used sponging with acetic acid in such cases. The credit of introducing cold bathing in fevers belongs to Dr. Parry of Liverpool; it had been dropped and temporarily forgotten, when it was revived by the Germans.

Dr. Rochester, of Buffalo, said it was fashionable to attribute increased tissue change, etc., to excessive heat, but thought other meteorological influences might be at work. When the sky is clear and temperature very high, cholera infantum is not so prevalent as when the air is loaded with moisture and the sky cloudy, though the thermometer may be lower.

ENUCLEATION OF OVARIAN CYSTS.

Dr. Julius F. Miner, Buffalo, N. Y., by invitation read a paper on the "Enucleation of Ovarian Cysts."

He stated that the enucleation of ovarian cysts was advocated by him seven years ago. It has been well received, but he thought his operation was not fully understood. After stating the relations of the ovarian cysts to the peritoneum and vessels, and the facility with which the cyst-wall is cut open, the tumor readily rolling out, he said that the fear of hemorrhage was unfounded, as the vessels moving from the peritoneal coat are capillary, and oozing is readily checked. Bleeding is more likely where the clamp is used and vessels cut across. A dry napkin to the collapsed cyst-wall checks the oozing, larger trunks are closed by torsion or ligature, and the contracted membrane is restored to the abdomen, giving no further trouble. If the operation fails, the clamp, cautery, or ligature may be subsequently applied. The diseased portion is removed, the living part returned; there is no pedicle outside, no need for drainage. Manipulation is no more difficult than separation of cystic growths from cellular tissue elsewhere.

(The paper contains the notes of several successful cases of enucleation of simple and multilocular cysts.)

The Chairman said no rule could apply to all cases. In some, enucleation was the only operation; he had been accustomed to regard it as a *dernier ressort*. He does not hesitate to tie the pedicle with whipcord and return into the abdomen; he had seen no bad result from the ligature, but thought the clamp gives greatest security.

Dr. Jas. P. White, of Buffalo, said where the pedicle is large and flat we cannot enucleate satisfactorily; where there is bleeding the hot iron is useful to sear the stump; it leaves less in the abdomen for absorption, and pregnancy occurred in his practice as often after the operation as he had lost patients.

Dr. E. R. Peaslee, of New York, did not think the vessels of ovarian tumors are capillary, as in some polycysts serious bleeding ensued. He had lost one patient by hemorrhage after enucleation, a vessel deep in the pelvis being broken off that could not be secured. He saw no objection to applying ligatures. In small cysts there is no advantage in enucleation, but he would adopt it in cysts adherent to the liver. He generally cut the ligature close, and had only one case where the pedicle sloughed. With this exception he never in these cases lost a patient from the ligatures.

Dr. G. Kimball, of Lowell, had used enucleation once, but in other cases he regretted not doing so. He generally uses a clamp, but adapts the treatment to the case.

Prof. Simpson agreed with this last remark. Best results would probably flow from cases where the abdomen is closed, and nothing left in its interior to cause irritation or future trouble.

Prof. Theophilus Parvin had had two cases of enucleation; one complicated by pregnancy, had consid-

crable bleeding checked by flannels dipped in hot water and freely applied. There is less risk in clamping than in returning large raw surfaces into the abdomen. Enucleation was valuable, but was not the only plan of treatment.

Dr. Miner said he found the vessels running in sulci and avoids them in enucleating. Where there is bleeding he resorts to torsion, but enucleation did not interdict subsequent use of hot iron, ligature, or clamp.

Wednesday, September 6th.—Dr. Barnes presiding. Dr. W. L. Atlee, Reporter, read his paper on the

TREATMENT OF FIBROID TUMORS OF THE UTERUS.

The subject was treated mainly from the standpoint of personal experience. The paper inquired into two general subjects: I. Tumors usually accompanied with hemorrhage, embracing (*a*), fibroids occupying the vaginal canal; (*b*), fibroids within the cavity of the uterus; (*c*), interstitial submucous fibroids; (*d*), interstitial fibroids proper; (*e*), recurrent fibroids. II. Tumors usually not accompanied with hemorrhage, including (*a*), interstitial subperitoneal fibroids; (*b*), sessile peritoneal fibroids; (*c*), pedunculated peritoneal fibroid; (*d*), interstitial cervical fibroid; (*e*), myomatous degeneration of the uterus; (*f*), fibro-cysts of the uterus. He considered the best mode of treatment, both surgical and medicinal, as the removal of tumors *per vias naturales*, by abdominal section, the propriety of extirpating a fibroid uterus by either of these methods, and an inquiry into the several agents which are supposed to control the growth of fibroid tumors.

Dr. J. L. Atlee, of Lancaster, Pa., stated that, through an error of diagnosis, abdominal section had been performed in his practice in two cases of fibroids, followed by recovery. In one the tumor was sessile, springing from the fundus; hemorrhage took place on one side, under the cyst-wall, giving a sense of fluctuation, and forcing the tumor into a half-moon shape. The growth, weighing 12 lbs., was removed, and a clamp applied. In the other case there was ovarian cyst on right side and a sub-peritoneal uterine fibroid (6 lbs.) in the left; both pedicles were included in the same clamp. He thinks this operation will soon be considered as legitimate as ovariotomy.

Dr. Alex. Dunlap, of Ohio, had noticed sub-peritoneal fibroids stopped growing after attaining a certain size—sometimes even receded. He described the ingenious plan for drainage outside the peritoneal cavity already alluded to in the RECORD several weeks since. He reported two cases of abdominal section for uterine fibroma; both died from want of drainage.

Dr. Kimball, of Lowell, Mass., was pleased with the suggestion just made, and with the general propriety of letting these growths alone. He reported a case of abdominal section for supposed ovarian cyst, which proved to be fibroma. The organ was extirpated, and a silk ligature applied. He was sent for six months later to remove the ligature, but found it firm; eventually it slipped inside, and gave no further trouble. The woman has gained 60 lbs. since the operation. He would not operate where the entire organ was involved and encroaches on the vagina, from fear of hemorrhage or exhausting suppuration. Instead of ligating the stump, he prefers the écraseur, and sears the stump with the hot iron. Very few cases authorize extirpation of the uterus. He had not seen any result from muriate of ammonia or ergot in sub-peritoneal fibroids, but one case got entirely well after a year's treatment by iodide of potassium injections into the uterus, three times a week (grs. viij.–x. to ℥ i.).

Dr. Peaslee, in a case of uterine fibroma not attended by any symptoms, unqualifiedly recommends muriate of ammonia; where the tumor is interstitial, Squibbs' fluid extract of ergot (gtt. x.–xij., t. d.). In hemorrhage there is no better remedy than ergot and chloride of iron. In a variety of polypus growing from the posterior wall of the cervix, projecting into the canal, and perhaps into the vagina, there is always serious hemorrhage from the pedicle. In such cases he uses the ligature and antiseptic washes. In the Negro race multiple fibroids are so numerous that in a Home in New York he is informed they are invariably found in cases over forty years of age. In cases of doubt in diagnosis, rectal exploration is justifiable. He had restored a retroverted gravid womb, at the fourth month, by its aid. In the discussion fibro-cysts should be separated from fibroids proper; the former generally spring from the posterior wall of the uterus and drag the organ upward, elongate the organ and bend it forward; this does not occur in simple fibroma, and is a diagnostic point.

Dr. H. Lenox Hodge, of Philadelphia, said: The best means of treating hemorrhage from uterine fibroma is to lift up the uterus and keep it in good position with an appropriate pessary. This treatment, introduced by his father, is followed by lessened bleeding, and in some cases by disappearance of the tumor, without internal medication.

Dr. C. B. King, of Pennsylvania, reported one case of operation by abdominal section and the clamp, with recovery.

Dr. Chas. Shepard, of Michigan, lost a case by not operating, and saved a second case by abdominal section and the ligature.

Dr. Geo. Sutton, of Indiana, read notes of one sub-peritoneal and one submucous fibroid cured by ergot hypodermically, and had one fatal case.

Dr. E. H. Trenholme, of Montreal, reported two cases of successful laparotomy, one fibro-cystic and the other fibroid.

The Chairman said that all agree that this operation should not be resorted to unless life is in danger, but in an extremity we are bound to extend any hope of relief. He had lost three cases within a year by attempting to remove the tumor through the vagina, and is extremely shy of operating unless he can remove every particle of the growth. Septicæmia occurring, may be remedied by frequent antiseptic injections and administration of quinia by the mouth.

THE THREE IMPORTANT OBSTETRICAL INSTRUMENTS.

Three obstetrical instruments were exhibited by the Secretary, sent by Prof. Lazarewitch, of Kharkoff, Russia, with a folio containing photographs and descriptions of their application. They consisted of a pair of short forceps, fitting together in a peculiar way; a double blunt hook, with an eye in one extremity, by which a fillet could be passed; and a peculiar cephalotribe and tractor, which to the Chairman appeared, in principle, to be an old English instrument revived. A vote of thanks was returned to Prof. Lazarewitch.

Thursday, September 7th, 1876.—Prof. Simpson in the chair. Prof. Wm. T. Lusk, Reporter, read a paper on the

NATURE, CAUSES, AND PREVENTION OF PUERPERAL FEVER.

Looking on puerperal fever as a generic term, he examined into its different varieties, making a distinction between non-infectious and infectious forms.

The non-infectious form was the result of traumatic injuries, old peritoneal adhesions, disregard of hygienic precautions, and mental influences; the infectious form was a septic disease. Local lesions were the usual, though not the necessary point through which the poison entered the system. He then inquired into the relations of bacteria to puerperal fever, the influence of erysipelas, scarlatina, diphtheria, etc., upon the puerperal state; and atmospheric influences. In studying the causes, he made deductions from civil and hospital statistics and private practice, and gave rules for prevention based on our knowledge of causes.

Dr. H. P. Yeomans, of Canada, remarked that lactic acid in the circulation would cause endocarditis, with deposits of fibrin on the valves; in such cases it is not necessary to suppose the presence of bacteria.

Prof. Goodell thought statistics of death from puerperal fever were unreliable in private practice, as physicians disliked to give certificates for it, and often gave instead one of the phenomena, as pleurisy or pneumonia, as the cause. This is one reason why the death-rate in Maternities from this cause is relatively high. Of 1,021 patients treated at the Preston Retreat, there had been only three deaths from puerperal fever; not one case of pelvic abscess. He isolates the patients as much as possible. In incipient cases he gives enough morphia or opium to subdue the pain; quinia is a favorite remedy, and alcohol given largely as an antiseptic and antipyretic, and to sustain the heart, as there is tendency to fatty degeneration.

Dr. Thos. W. Gordon, of Ohio, in a large practice had seen only two cases of puerperal fever, but had seen many incipient cases arrested by ergot, quinia, and alcohol.

Prof. Byford said, cases of puerperal fever belonged to three principal classes: those arising from within the patient or her immediate surroundings; those occurring in the same neighborhood, endemic cases, the cause being zymotic, as in hospitals and poor neighborhoods. When this form prevails in hospital, with ordinary precautions he does not dread carrying the disease among his private patients. The third class of cases occurs under peculiar epidemic influences, as during prevalence of the Black Tongue in Indiana, in 1839, when in the first part of the epidemic all the puerperal cases died. There was no lack of ventilation or cleanliness; they were not communicated, as they occurred miles apart in the practice of different physicians, and in cases unattended by physicians. There must have been a wide-spread epidemic influence.

Dr. J. L. Atlee quoted three cases where puerperal fever was communicated from erysipelas.

Dr. Jas. P. White testified to the contagious nature of the disease, and its connection with erysipelas. No physician has a right to go from a case of erysipelas, or of puerperal fever, and attend a case of confinement.

Prof. Trenholme had five cases of puerperal fever, all of which recovered under careful treatment and large doses of morphia. Of six hundred cases of obstetrics, he had lost but one from any cause whatever.

Dr. Robt. Burns, of Philadelphia, recommended venesection in cases that would bear it, and internally, opium, gr. i., calomel, gr. ss., hourly, and a poultice to the abdomen.

The Chairman said, in all the works on the subject error creeps in when they discuss puerperal fever. The chapter on this subject should be entitled "Fevers of the Puerperal State," and extend from simple mastitis to those accompanied by poisoned blood. Many cases called puerperal fever were typhoid fever, occurring in the puerperal state, and more rapidly fatal on account of lessened power of resistance. Apart from fever caused by special poisons, which might suggest a division of cases into typhoid puerperal fever, scarlatinal puerperal fever, and those due to erysipelas, measles, etc., others closely resemble the fever following surgical operations. It would be interesting to inquire if soldiers wounded early in the fight, while fresh and vigorous, were less liable to surgical fever than others wounded in the same battle after hours of fatigue and exhaustion. An analogy exists here between such cases and the puerperal condition, so far as relates to dangers to which puerperal women are exposed from short and long labors.

We should study all the sources of this disease that we can find in our daily rounds. Most of the germ destroyers are acids,—carbolic, sulphurous, salicylic, etc. There is nothing better to disinfect the hands than common vinegar; after extraordinary exposure, the clothing should be exposed to sulphurous acid fumes.

Prof. Lusk stated, that masses of bacteria had been found on the cardiac valves in cases examined. He used Labarraque's solution to disinfect his hands, washing them to the elbows, perhaps twenty times a day during an epidemic. He had never carried the disease from hospital to private patients.

Dr. Fred. Semeleder then read a paper on

ELECTROLYSIS, ESPECIALLY FOR THE CURE OF OVARIAN CYST.

After some general remarks on electricity, he gave an account of the effects of electric currents on solutions of salt or albumen, stating that the positive and negative pole act somewhat differently, and that from this circumstance different indications may be derived. He then passed to the cure of ovarian tumors by electrolysis, and gave a short statement of six cases he had successfully treated. The method is really new, though cases were published in 1859; they were long forgotten; the profession took no notice of them. No inflammation, no pain, no adhesions were caused; his patients were never put under chloroform, nor confined to bed. The cures required from one to five months; the patient is not deprived of one of her most interesting organs. He concludes emphatically: It is a case of conscience to try electricity, before ovariotomy is resorted to, as a patient will not find herself in a worse condition for the operation if electrolysis prove unsuccessful, while a little delay is an insignificant evil in comparison to the risks of ovariotomy.

Friday, Sept. 8th.—Prof. Simpson in the chair. On motion, it was decided to have all the papers read *seriatim* before discussion.

Dr. Simon Fitch, of New York, read a paper on

"PARACENTESIS, ASPIRATION, AND TRANSFUSION."

It considered: 1. Paracentesis as it was, with the old trocar; 2. Paracentesis and aspiration as they are with modern instruments; 3. Paracentesis, aspiration, and transfusion, as they should be with available apparatus. The following conclusions were given: 1. The old trocar, with big head and split canula, should be esteemed a relic of the past. 2. Modern trocars chiefly used are, either the pointed single tube, too often used in aspiration without a guard to cover the point, which is very dangerous; or the same guarded by a canula on the outside, which if thick is uncertain to enter; if thin, is only somewhat less hazardous than the point itself. 3. The trocar of the future should

be easy of insertion, harmless when inserted, safe as a probe or sound, competent for the free passage of fluids, adapted to the aspirator, and certain to have a wound ready to heal. A series of instruments under the general name of dome-trocar was described by him, and its mode of application and advantages explained at some length.

It is said by Dr. Fitch to be adequate to make transfusion and other critical operations simpler, quicker, and safer, and so advance the efficiency and safety of paracentesis, aspiration, and transfusion of the future.

UTERINE HEMORRHAGE AND INVERSION.

Dr. E. H. Trenholme, of Montreal, then read a paper on "Uterine Hemorrhage," and Dr. James P. White, of Buffalo, one on "Chronic Inversion of the Uterus." Both were interesting and valuable contributions.

RETROVERSION OF THE GRAVID UTERUS.

Dr. T. F. Rochester, of Buffalo, reported a case of retroversion of the gravid uterus, between the fourth and fifth months. So completely was the organ capsized that it was impossible to find the os uteri. There was the usual hemorrhage from the bladder. It was found or judged impossible by position and manipulation to replace the womb. It was decided, on consultation with Prof. James P. White, to puncture or tap it, through the wall of the everted fundus, with a capillary trocar. This procedure was followed by the happiest results; in three days thereafter a fœtus nine inches long was expelled, and the mother recovered without an unfavorable symptom. Two months afterwards the womb was replaced with Simpson's sound and retained *in situ* by a hard rubber cradle-shaped pessary. The patient continues perfectly well, but has not since become pregnant.

Dr. John L. Atlee cautioned against puncturing every retroverted gravid uterus. He recalled a case retroverted by full bladder easily restored after catheterization and which went on to full term. He had seen only one case of inversion in fifty years. He was summoned in consultation in an acute case, but found her in a condition of collapse that forbade operation; after advising opium in full doses, he left. Much to his surprise he heard some time afterwards that the woman did not die, but was again pregnant. He did refer to this as spontaneous reduction, but not purely natural; as the womau was again pregnant, the *modus operandi* was left to individual speculation.

Dr. W. J. Heddens, of Missouri, has reduced two recent cases of inversion with the air-bag.

Dr. W. L. Atlee reduced in ten minutes an inverted uterus of several months' standing, with the blunt end of the large dome-trocar of Dr. Fitch. He reported two other cases of retroversion of the gravid uterus caused by distended bladder, both easily restored: one went to full term; the other, complicated by sphacelus of the bladder, miscarried.

A NEW CLAMP.

The Secretary exhibited a new clamp for ovariotomy, by Dr. Alex. Strubel, of Dresden, consisting of two sickle-shaped segments of steel drawn together by a screw, to secure the pedicle.

After passing a vote of thanks to Dr. Barnes and Prof. Simpson for their services in the chair, the Section adjourned *sine die*.

SECTION OF DERMATOLOGY AND SYPHILOLOGY.

Monday, Sept. 4th, 1876.—The Section was organized, Prof. Jas. C. White, of Harvard University, taking the chair, Dr. Arthur Van Harlingen, of Philadelphia, Secretary.

VARIATIONS IN SKIN DISEASES IN DIFFERENT COUNTRIES.

A paper on "Variations in Type and in Prevalence of Diseases of the Skin in Different Countries of equal Civilization" was read by James C. White, M.D., Professor of Dermatology in Harvard University, Reporter. This was based on statistics drawn from reports of leading dermatologists of Europe and America, embracing 50,000 cases from abroad, with 12,000 observed in this country.

As a result of examination and comparison of these statistics, he deduced certain conclusions embraced in a series of propositions, as follows:

1. Certain obscure affections, the etiology of which is little if at all understood, even in those parts of Europe to which they are mostly confined, may be regarded as practically non-existent among us. Of such are prurigo, pellagra, and lichen exudativus ruber.

2. Certain diseases directly connected with and dependent on poverty and habits of personal uncleanliness are less prevalent in the United States than in those parts of Europe of which we have sufficient statistical information for comparison. Examples of this class are the animal parasitic affections especially.

3. Some cutaneous affections of grave character, dependent on, or a part of serious constitutional disorders, are of less frequent occurrence and of milder type amongst us than in Europe in general, or those parts of it where they are endemic. Lupus, the syphilodermata, and leprosy are the most marked instances of this class.

4. Certain disorders of the skin, especially those connected more immediately with its nervous system, are apparently more prevalent with us than in Europe. The most notable examples of the former are: seborrhœa, acne, and possibly heat rashes; of the latter, herpes, urticaria, and pruritus.

Considerable discussion ensued regarding some of these points. Dr. Duhring, of Philadelphia, thought that massing the figures from the three cities, Boston, Philadelphia, and New York, gave a fallacious impression with respect to diseases in any one of these cities.

Dr. Bulkley, of New York, replied that the same discrepancy would be found to exist between the statistics of successive years in the same institution. He thought by collating the figures derived from reports of these localities, extending over a series of years, as the reporter had done, a very fair idea could be obtained of the prevalent skin diseases of the country.

Some discussion also took place on the use of the term morphœa by the reporter, and the relations borne by this disease to other affections sometimes called by the same name, as Addison's keloid, linear atrophy and scleroderma. Various opinions were expressed by Drs. Bulkley and Duhring, and by the reporter, the conclusion finally reached being that the term morphœa had been used in the sense generally understood by American dermatologists. The reporter's propositions were then taken up one by one.

On the subject of some of the affections mentioned, as prurigo and leprosy, no difference of opinion seemed to exist relative to the occurrence of these affections now in America. As regards the latter, Dr. Bulkley related a case which had come under his observation, occurring in a person of healthy American parentage, who had never been sixty miles away from New York. Cases were alluded to by the reporter as occurring in some of the Southern States, as well as the well-known

leper colony in Nova Scotia. As regards the severity of syphilis, as it is found in this country, the different members of the Section seemed to have had a different experience. Dr. Duhring said he was quite sure he had seen as large a proportion of very severe cases of this disease in Philadelphia as he had seen abroad.

The various propositions presented by the reporter were finally passed, it being placed on record, however, that the sense of the Section regarding the third proposition was understood to be, that lupus vulgaris is of a milder type and less prevalent in this country than in Europe; that leprosy is not sufficiently known to warrant an expression of opinion; and that, upon the subject of the syphilodermata, the Section differ from the reporter.

Dr. Bulkley offered the following additional proposition, which was adopted by the Section:—The type of certain acute congestive and nervous diseases of the skin is more severe in this country than abroad.

The chairman called attention to a paper entitled "Verugas, a Disease peculiar to Peru," by Dr. Ward, of Lima, which had been sent to the Section. On motion, the paper was referred to a committee.

Tuesday, Sept. 5th.—The Section met at 2 o'clock. Lucius Duncan Bulkley, M.D., of New York, Reporter, read a paper on the question,

ARE ECZEMA AND PSORIASIS LOCAL DISEASES, OR ARE THEY MANIFESTATIONS OF CONSTITUTIONAL DISORDERS.

He considered the nature of the eruption in constitutional disorders affecting the skin, as in the contagious fevers, syphilis, etc., and also the characteristics of local diseases; also the microscopic anatomy of eczema and psoriasis. He then studied the clinical history of eczema and psoriasis, according to age, sex, location, relapses, hereditary transmission, gouty and rheumatic symptoms, urinary disturbances, bronchitis, etc. He then examined into the clinical history of local diseases, epithelioma, verruca, parasitic and mechanical diseases of the skin, etc., the effect of local and constitutional treatment, etc. The propositions brought forward by him aroused much opposition, and were debated one after another, the discussion lasting the whole afternoon. The debate seemed chiefly to turn upon the nature of eczema, and the various pathological theories connected with dyscrasia, diseases of the blood and the cellular pathology, as bearing upon this affection.

The propositions as finally adopted by the Section were as follows:

1. Eczema and psoriasis are diseases *sui generis*, and are not to be confounded in any way with other states; as the former with artificial dermatitis, and the latter with the eruptions of syphilis, scaly eczema or leprosy.

2. Eczema and psoriasis cannot own a double independent causation or nature, at one time local and another constitutional; but with other diseases, they may have a twofold cause, namely, a predisposing and an exciting.

3. Eczema and psoriasis in many of their features resemble the accepted constitutional diseases more than those recognized as local.

4. Local causes play an important part in the etiology of eczema; they are probably inoperative in psoriasis.

5. Certain relationships between psoriasis and epithelioma have been claimed, which require much further investigation. At present they are not established, and are no proof of the local nature of psoriasis.

6. No direct causal connection has yet been demonstrated between the scrofulous state and eczema and psoriasis.

7. Local treatment is often insufficient alone to remove the lesions of eczema and psoriasis, and cannot prevent or delay relapses.

8. The success of local treatment in eczema and psoriasis does not demonstrate the local nature of these affections.

9. Constitutional treatment alone and singly can cure many cases of eczema and psoriasis, and prevent or delay relapses in a certain proportion of cases; under constitutional treatment it is intended to signify every agency not properly placed among local measures.

10. The total weight of argument is that eczema and psoriasis are both manifestations of constitutional disorders, and not local diseases of the skin.

Prof. Rudnew, of St. Petersburg, then read a paper entitled,

"WHAT IS THE DISEASE KNOWN AS LUPUS?"

by Dr. Woskrensky, of the Institution of Pathological Anatomy, St. Petersburg, under Prof. Rudnew's directions. The name was originally loosely applied, just as "sarcoma," "cancer," etc., were. The changes of the tissues in lupus have no signs by which it can be considered a separate and independent disease. It is merely a name applied to several species of tumors. From personal observations in facial cases, he considered that all the different varieties might be classed under three divisions:—1, a form which is simply a horny cancer, and incurable; 2, adenoma simplex, or confounded with the cancer; 3, granuloma syphiliticum, easily cured.

Wednesday, September 6th.—Freeman J. Bumstead, M.D., late Professor of Venereal Diseases at the College of Physicians and Surgeons, New York, Reporter, read a paper on

THE VIRUS OF VENEREAL SORES; ITS UNITY OR DUALITY.

The following propositions were stated by the reporter:

1. The virus of venereal sores is dual.

2. Venereal sores may be due to the inoculation of the syphilitic virus, and also to the inoculation of the products of simple inflammation.

3. These two poisons may be inoculated simultaneously.

The second proposition aroused a lively debate, the reporter being understood to express the view that there was no specific chancroidal virus. At the suggestion of the chairman, the proposition was divided into two sections. The first of these was passed without discussion; but as to the second, all that portion of the original proposition which follows the word "virus," was, after long debate, rejected by the Section.

In connection with the second proposition, Dr. Bulkley offered the following, which was adopted by the Section:

The present state of science has demonstrated that suppurative inflammatory lesions resembling chancroids may be produced on different portions of the body by inoculation with simple pus from various lesions.

A paper by Dr. Drysdale, of London, bearing the

same title as that of Dr. Bumstead, was then presented by the Secretary, and, on motion, was passed by title.

The Secretary then read a paper entitled

LEPROSY IN THE SANDWICH ISLANDS.

By Dr. F. H. Enders, Government physician. They believed it was introduced from China, but probably this was not so. The writer was unable to say positively whether it was a disease *sui generis*, or a form of syphilis, although he inclined to the latter view. He had seen over four hundred cases, all of whom except two had had syphilis. Two forms of leprosy were met with, the anæsthetic and the tubercular, cases of which were cited. Many interesting facts in its history, treatment, etc., were given.

SEBORRHŒA.

Dr. Heitzmann, of New York, read a paper on "The Treatment of Seborrhœa." A discussion upon the subject of this paper ensued, in which various members of the Section gave their experience in the treatment of the affection.

THE CONSTITUTIONAL TREATMENT OF SYPHILIS.

Thursday, September 7th. The Section met at two o'clock P.M. A paper was read on "The Treatment of Syphilis with Special Reference to the Constitutional Remedies appropriate to its various Stages; the Duration of their Use, and the Question of their Continuous or Intermittent Employment;" by E. L. Keyes, M.D., Adjunct Professor of Surgery and Professor of Dermatology in Bellevue Hospital Medical College, New York, Reporter.

The propositions presented were as follow:

Negative conclusions: views for which there would seem to be no foundation in fact.

1. Syphilis commencing mildly needs but little treatment, and does not require mercury.
2. Mercury given internally is necessarily debilitating.
3. Mercury is only useful in secondary syphilis.
4. Iodide of potassium is of considerable value in secondary syphilis.
5. Iodide of potassium is of no value unless preceded by the use of mercury.
6. Iodide of potassium acts by liberating mercury which has been lying latent.

The following positive conclusions, which in the present state of our knowledge may be affirmed, were then enunciated by the reporter, and laid before the Section.

1. Mercury is an antidote to the syphilitic poison, and of service in controlling all its symptoms in all, even the latest stages, of the disease; its power over gummata being least, and not to be relied upon.
2. Mercury in minute doses is a tonic.
3. Iodine cures certain symptoms of syphilis, but does not prevent relapses.
4. Mercury long continued uninterruptedly, so far as practicable in small doses from the time of earliest eruption, constitutes the best treatment of syphilis.

These propositions gave rise to much debate, the discussion for the most part including the question of continuous or interrupted methods of treatment. It was finally conceded that the statement was of a scientific nature, and suggested the object to be aimed at, rather than that which is generally attainable.

Dr. Drysdale's paper, bearing a similar title to that of Dr. Keyes, was, on motion, accepted by title.

The paper by Dr. Ward, of Lima, entitled "Verugas a Disease peculiar to Peru," was, on recommendation of the committee appointed to examine it, passed by title.

Friday, September 8th.—The paper of the day was by Dr. S. Engelsted, of Copenhagen, and was entitled, "Measures to prevent the Propagation of Venereal Diseases in Denmark."

Some discussion on the subjects presented in the paper ensued, after which the following preamble and resolutions were proposed by Dr. Bulkley and adopted by the Section:

Whereas, After an interesting and valuable paper by Dr. Engelsted, of Copenhagen, in regard to the prevention of venereal diseases in Denmark, in which the laws which have been in successful operation there are given in full, with statistics showing very favorable results;

Whereas, At recent meetings of the American Medical Association, Drs. Gross and Sims have advocated measures in reference to their control; therefore,

Resolved, That this Section do recommend that the International Medical Congress, convened at Philadelphia, Sept. 4th–9th, 1876, do appoint a committee to consider the subject more fully, to collect statistics and data, and to report through the medical press, with a view to influence laws which shall have the aim of diminishing and rendering less severe venereal diseases throughout the world.

(These resolutions were presented to the Congress at its final session, but were not adopted.)

The Section then adjourned *sine die*.

SECTION OF BIOLOGY.

Monday, September 4.—The Session met, Prof. S. E. Chaillé, of New Orleans, in the chair; Dr. James Tyson, of Philadelphia, Secretary.

MICROSCOPY OF THE BLOOD.

Prof. Christopher Johnston, Reporter, read a paper on this subject, in which he inquired into the original source of blood in vertebrates; and the elements of blood in them. The normal elements having form were exclusively considered, from two points of view: that of anatomy and physiology, and of medical jurisprudence. He discussed the genesis of corpuscles; the form of colored corpuscles, and their structure; leucocytes; the size of colored corpuscles and their enumeration, and the relation of the colored blood-corpuscles to medical jurisprudence.

The discussion which followed was almost a repetition of that had at the recent American Medical Association meeting, and was confined to the medico-legal application of our knowledge of the size of the red blood-discs. The reporter took the ground that it was impossible to identify by their size the red discs of human blood from those of other mammals nearly related in size.

The chief point at issue was stated by Dr. J. G. Richardson, of Philadelphia, to be as follows:

He said, if his memory served him correctly, Prof. Johnston had mentioned that when Dr. Woodward showed him a series of specimens of blood-corpuscles, including samples of guinea-pig, dog, and man's blood, he found it impossible to discriminate one from the other. This result was exactly what he would have anticipated, but he would like to ask Dr. Johnston whether, in case Ananias (by way of complete antithesis to Dr. W.) offered him a slide for inspection, and concealing the label, told him it was sheep's blood, he could not, if the corpuscles proved on measurement to be $\frac{1}{3200}$ of an inch in diameter, say most emphatically, "Ananias, you lie?"

Dr. Didama, of Syracuse, New York, was inclined to agree with Dr. Richardson's general views on the subject.

Dr. Tyson, of Philadelphia, thought we might go so far as to say that such blood was more likely to be the blood of man than of an ox, or sheep, or pig, but would not be willing to say positively such blood was derived from a human being rather than from one of the animals mentioned; he could not but think, with his present knowledge, there might be circumstances in the drying, age, or texture of the fabric on which they lay, which could make it impossible to distinguish human blood-corpuscles from others, even as much smaller as those of the ox and sheep.

Dr. Joynes, of Richmond, Va., inquired of Dr. Richardson how far the original character of corpuscles, dried on cloth or similar textures, could be restored by maceration, and expressed the fear that difficulties of this kind might cause error.

Dr. Richardson replied that it had been pretty well determined that while corpuscles may shrink from five to ten per cent. in their original diameter in drying, it had not been found that they swell or increase their diameter by soaking. In conclusion, he exhibited under a Holmes Class microscope a red blood disc from the Amphiuma tridactylum, the hæmatocrystallin of which had crystallized in the upper end of the corpuscle, whilst the nucleus occupied the lower extremity, leaving the membranous corpuscle (cell wall) hanging in folds like a half flaccid balloon between them.

EXCRETORY FUNCTION OF THE LIVER.

Tuesday, September 5th.—Prof. Austin Flint, Jr., of New York, Reporter, addressed the Section on this subject. It was an interesting re-statement of the well-known views of the reporter, that cholesterine is an excrementitious substance, bearing the same relation to the liver that urea bears to the kidneys; is discharged in the bile into the small intestine; is transformed during digestion into another substance (stercorine), and, as stercorine, exists in the fæces.

Prof. Dalton, of New York, then followed in some interesting remarks on the "Importance of Physiological Chemistry in Physiology," and alluded to Dr. Flint's investigations as being in this direction. He gave also a history of the succession of discoveries connected with this subject, beginning with the finding of cholesterine in gall-stones, and culminating in Dr. Flint's elaborate investigations and discoveries.

Dr. Flint's views were generally concurred in.

Wednesday, Sept. 6th.—Prof. Rudnew, of St. Petersburg, Russia, read several papers appropriate to this Section, from investigations made under his direction:

One by Dr. Jäntchich, on the "Termination of the Nerves in the Human Skin."

One, by the same, on the microscopical anatomy of the nervous apparatus of the bronchia and lungs; and two other papers on kindred subjects; but the descriptions being minute, although interesting, do not admit of the possibility of an abstract.

PREVENTION OF FUNGOUS GROWTHS.

Dr. Joseph G. Richardson, of Philadelphia, then read a paper on "Fungous Growths in Solutions for Hypodermic Medication, and their Prevention by Salicylic Acid."

He stated that the atoxic property of salicylic acid, superior to most powerful antiseptics, suggested its employment to prevent growth of tufts of fungi in morphia solutions, and in order to test its precise value, he devised a series of experiments, in which different quantities of salicylic acid were added to the usual Magendie's solution, other portions of the same fluid being allowed to remain unprotected for sake of comparison. His results showed that even in summer morphia solution remained for over a month almost free from fungous growths, when it contained one grain of salicylic acid to the ounce of liquid; when the quantity of acid was doubled, the fluid was preserved entirely clear of fungi. He also proposed the use of salicylic acid as a preservative for medicinal solutions of other alkaloids or salines, and for vegetable infusions.

In reply to a question of Prof. Dalton, Dr. Richardson said that although he had repeatedly injected his own arm with solutions containing fungi, he had never experienced any inconvenience either by formations of abscess or by general symptoms attributable to it.

Thursday, Sept. 7th.—Prof. Harrison Allen, of Philadelphia, Reporter, read a paper on the "Mechanism of Joints," which contained many novel suggestions and facts. It was shown, for instance, that when the ball is supported by the socket, as at the occipito-atloid articulation, rest is suggested, but when suspended from the socket, as at the temporo-maxillary articulation, motion is suggested. In illustration, the etiology of fracture and dislocation was examined. Articular surfaces were studied in three classes: axial, actinic, and lateral, and these terms defined with examples. A correct knowledge of the symptomatology and treatment of diseases of the joints was shown to be dependent on a true conception of the complex nature of articular surfaces.

Prof. Dalton said the paper contained much that was new to him, and explained some points which had long been unexplained, and that the same reasoning might also be extended to the ligaments. While dissecting joints as a student of medicine, he had been struck with the fact that in flexing and extending the limbs, it was impossible to say when certain parts were put upon the stretch and when they were not. He thought this might be explained by supposing the internal surface of the capsule to be made up of innumerable facets brought successively into action, just as Dr. Allen had shown to be the case with the curved articular surfaces of the bones.

With the exception of several papers on Friday, presented by Prof. Rudnew, of St. Petersburg, from Russian investigators, on "Sclerosis of the Arteries," "Cancer in the Lymphatic Glands," etc., no other paper of importance was discussed in this section.

SECTION OF SANITARY SCIENCE.

Monday, September 4th.—The Section had assigned to it as Chairman, Dr. Stephen Smith, of New York, and Dr. Ezra M. Hunt, of New Jersey, as Secretary; Dr. Billings, U.S.A., and Dr. Baker, of Michigan, as Vice-Presidents. In the absence of Dr. Smith, Dr. Billings presided.

DISEASE GERMS.

The Session was almost entirely occupied by the paper of Dr. T. E. Satterthwaite, of New York City, Reporter, on "Disease Germs." It presented in a concise way, the vegetable germ theory, the bioplasm theory, and the physico-chemical theory. A fair exhibit was given of the arguments adduced in support of each of these. The author recounted his own experiments and those of Dr. Edward Curtis, of New York City, and presented diagrams of the various appearances under the microscope, and specimens of vacuum-tube experiments. Right emphasis was laid upon the point

that motion does not always indicate life. Fluids were shown still to be poisonous after such filtration as would separate vegetable organisms.

The following general topics were discussed:—The agency of minute vegetable organisms in fermentation and putrefaction; epidemic diseases of plants and animals in their relation to such organisms; rapid multiplication of bacteria *pari passu* with the rapid spread of disease manifestations throughout the system; constant ratio between the most active changes in so-called septic diseases, as pyæmia, erysipelas, and puerperal fever, with numerical increase in bacteria at points involved; can any strictly chemical substance be a fever producer; bacteria and disease poisons, their capacity for successfully maintaining active properties; inoculation of bacteria in healthy tissues.

The following special topics were also considered:—

1. Bacteria: their classification, diagnosis, and appearances under varying conditions.

2. Poisonous fluids of infective diseases, their physical properties and the solid particles contained in them.

3. The value of vacuum-tube experiments.

4. How far are the bioplasm, or physico-chemical theories competent to explain spread of infective diseases?

5. Poisons of special diseases, as cholera, small-pox, carbuncular diseases of men and animals, typhoid and relapsing fevers, and diphtheria, are not proved to be dependent on these minute organisms. The poison of diphtheria membrane, for instance, killed twenty out of twenty-seven rabbits, when no bacteria were present.

The paper was discussed by Drs. Henry Hartshorne, of Philadelphia, Hunt, of New Jersey, Billings, U. S. A., and others.

Dr. Billings preferred the term "minute vegetable organisms" to the terms bacteria, microzymes, etc., so often used, as these latter seemed to state a theory.

Dr. Hunt quoted Pettenkofer as saying, "what germs are, we do not know." The bacteria found in various infective diseases cannot be distinguished from one another, or from those of healthy persons. Billroth makes them all forms of one mother plant. The views of Klein and the hope of Simon that the contagion of enteric fever had been found, were alluded to, and also those of Oertel in reference to diphtheria. Dr. Hunt claimed that fermentation and putrefaction must be studied as separate decompositions, and that vegetable organisms were most frequently the effort of nature to dispose of the débris of disease, and so conservative—except where, from great accumulations, they might become themselves a source of evil.

Dr. Hartshorne expressed the view that we did not sufficiently recognize this compensating effort in nature; but still as there are venomous insects that have no conservative work, so there are such factors of disease.

The germ theory also came up prominently in the Surgical Section in connection with the antiseptic treatment of Prof. Lister. The Sanitary Section adopted the conclusions proposed by Dr. Satterthwaite after slightly modifying them, and the paper was recommended for publication.

The conclusions were as follows:

1. That so far as inquiry has been made into the nature of the active principles in infective diseases, it is probable that in a certain number the matter is *particulate* or *molecular* in form, and, in the instances named, in no sense a soluble substance.

2. That in regard to the *causes* of septicæmia, pyæmia, puerperal fever, erysipelas, and hospital gangrene, and in cholera, small-pox, the carbuncular diseases of men and animals, typhoid, relapsing fevers, and diphtheria, there is not satisfactory proof that they are necessarily connected with minute vegetable organisms.

3. That the real nature of these causes is still uncertain.

VITAL STATISTICS OF BUENOS AYRES.

A paper on this subject was offered by Dr. Rawson, of that city, and referred to a committee for examination. Abstracts were read from it the next day. It contained some interesting matter, but did not, amid the imperfection of registry, throw much light on the subject. It noted the fact that offal, sometimes to the amount of 390 tons daily, was carried out of the city and burned. It insisted on the importance of looking to the health of native-born children in every country, as these are generally better members of society than immigrants. The frequency of trismus nascentium was noted, causing at times 6.5 per cent. of all the mortality. Parts of the paper were worthy of a place in the Transactions, and it was referred for publication.

HOSPITAL CONSTRUCTION AND VENTILATION.

Tuesday, Sept. 5th.—The Section was occupied with the paper of Dr. Stephen Smith, of New York, Reporter, on these subjects, and with a detail of the more recent plans for the "Johns Hopkins Hospital," by Dr. Billings, of Washington.

Dr. Smith's paper was designed to show the very advanced position of that art at the close of the century 1776, the comparatively little progress made during the century 1876, and the present status of hospital reform. The position of the art in 1776 was illustrated by:—*First.* The New York Hospital, a pavilion hospital, then recently destroyed by fire, which had been built according to plans brought from England by Dr. John Jones; and has not been surpassed in its essential features, especially in regard to the separation of the sick by large surface and cubical areas. *Second.* The report of Committee of French Academy of Sciences, 1788, on rebuilding the Hôtel Dieu, giving in much detail the pavilion plan. These embodied in its highest state of perfection what is now recognized as the pavilion hospital. Little progress was made during the nineteenth century, except the building of the Lariboisière, of Paris, on the pavilion plan, until the Crimean war, when the pavilion system was again revived by Miss Nightingale. While the reform of military and quarantine hospitals is all that can be desired, too little progress has yet been made in location and construction of civil hospitals. Propositions were submitted embodying latest suggestions of science and experience.

Dr. Billings, after a lucid explanation of the plans of the Johns Hopkins Hospital as at present suggested, and the reasons therefor, compared at length the different plans of ventilation, and showed why the fan was often more available and more adapted for combination with natural modes than the aspirating method. He drew attention to the tendency of air to cling to surfaces, and presented the results of some anemometer and other experiments as to heating and ventilation conducted within the past year at a hospital in Washington.

Many questions were asked and considerable discussion ensued, in which Drs. Henry Hartshorne, Bowditch, Hewitt of Red Wing, and others participated. Drs. Bowditch and Hewitt especially insisted that we depended too much on physicists and experiments, and that, after all, the sensations of the patients and the

experience of the physician were more reliable. Others regarded mere sensation as unreliable, and only to be compared with other indications. The paper was referred to the Congress for publication, without formal adoption of its conclusions.

GENERAL SUBJECT OF QUARANTINE.

On Wednesday, September 6th, the paper on Quarantine, with particular reference to cholera and yellow fever, by Dr. Woodworth, Supervising Surgeon-General, Marine Hospital Service, Reporter, with its discussion, occupied the whole session.

After reviewing briefly the practice of quarantine in the past, and as at present administered, the mode of propagation of cholera and yellow fever were discussed with the view of arriving, as near as possible, at what precautions are necessary and what restrictions superfluous in the administration of quarantine.

The chief points were the practice and methods which should be pursued to secure greatest protection to public health against cholera and yellow fever with the least restriction upon commerce. In this connection were considered the want of prompt information to threatened ports of the shipment of passengers or goods from infected districts; the question of time as an element in quarantine; the value and practice of disinfection; the importance of municipal sanitary co-operation; and what may be gained by imparting to masters of vessels correct views of sanitary measures to be enforced by them in outbreaks of cholera or yellow fever on shipboard, etc.

The papers involved the chief laws of sanitation, of contagion, and of specifics of disease, and had material for the fullest discussion, in which Drs. Vanderpoel, Hartshorne, Murray, and others took part. Dr. Vanderpoel's personal experience was listened to with interest, and other speakers showed an intelligent acquaintance with the defects of ship regulations. Some discussion took place as to the relation of filth to disease, and the distinction was urged between filth as a nest, and filth as a creator of the disease germ, and so an originator of a specific disease.

With some slight modifications, the conclusions presented were adopted, and the paper highly commended for publication.

DISPOSAL OF SEWAGE.

Thursday, September 7th.—The Section was occupied with the subject of "The Disposal of Sewage." Dr. Henry Hartshorne, Reporter, read a paper setting forth the various plans for this object, giving preference to the water method and to soil filtration through drained land, so that value to crops and perfect conveyance to water-courses could be secured.

Dr. S. W. Gross presented a plan of sewer ventilation, suggested by a Philadelphia engineer.

Dr. J. G. Kerr, of China, spoke of Chinese methods. The chief idea in China was to dispose of offal above ground, while we sought to place it below ground. He believed epidemics were not, as a rule, so severe in Chinese cities, because they avoided soil saturation and soil pollution.

Dr. Johnson, of Salem, Mass., noted the evils arising from inflowing tide meeting outflowing sewage, and so often causing sewer pollution. The conclusions of the paper were modified so as not to give exclusive prominence to any one method of disposal.

UNIVERSAL PHARMACOPŒIA.

Dr. Squibb, of Brooklyn, read a paper on this subject, which, in the absence of a materia medica or pharmacy Section, had been assigned to preventive medicine. Mistakes arise from confusion in nomenclature. Dr. Squibb showed in what respects a universal pharmacopœia would be of service, and yet recognized such embarrassments as to preclude a hasty attempt in that direction. In the meantime he claimed that greater uniformity should be sought and unnecessary diversity of names be avoided.

PHARMACY AND MEDICINE.

Dr. Hunt, of New Jersey, also read a paper on the evils arising from separation of pharmacy and medicine. He claimed that pharmacy, like any specialty of medicine, should be a department rather than accessory, and should be replaced within the profession, and so held accountable to its ethics. It was ably discussed by Drs. Steiner, of Maryland, Squibb, Hartshorne, and others. All the papers were referred for publication.

WEIGHTS AND MEASURES.

Friday, September 8th.—Dr. Squibb presented an able paper on "The Medical System of Weights and Measures." It showed the feasibilty of the system, and the methods by which its adoption could be facilitated. Its adoption by two prominent nationalities already, indicates its more extended use, and this should be diligently encouraged.

Dr. Bowditch noted the fact that it had met with some opposition from a prominent scientist of Boston, and Herschel had also made some forcible objections to it. Any system which is more or less arbitrary can have real objections filed against it. But this works so well in practice, that few practical operators now dissent.

MEDICAL MISSIONS.

Dr. Kerr, of China, read an interesting paper on "Medical Missions," reference being had to sanitary and other regulations in China and other countries. The paper was discussed by Dr. Harris, of New York, and such parts of it as referred to medicine were ordered to be referred for publication. The Section then adjourned *sine die*.

Correspondence.

"THE CAUSE OF CHOREA."

To the Editor of The Medical Record.

In the communication of Dr. Allen M'L. Hamilton under the above title, which appears in The Medical Record of Sept. 16th, the writer makes a few points, to each of which, though not in the order given, I desire to call attention.

Dr. Hamilton remarks: "Surely the etiology of chorea is well understood, though its pathology is not so clearly settled." Yet Dr. T. E. Anstie (*Lectures on the Nervous System*) says: "The *causation* and pathology of chorea form one of the most puzzling subjects which medical inquiry has ever encountered," and the learned author further adds: "When we have stated the very obvious facts that chorea is a disease of some portion of the central nervous system, and that the circumstances favoring its occurrence are all of them of a debilitating kind, *we have said very little, as you will allow.*"

Whether Dr. Hamilton, in his brief catalogue of "circumstances of a debilitating kind," has after

all said *very much*, I leave for him to settle with the distinguished author.

Dr. Hamilton promulgates the doctrine that if we allow that in chorea the fault lies in the eyes, we must of necessity ignore the fact that chorea is often cured by medicines.

The same kind of reasoning would prove that no man could be cured of a fever and ague so long as he remained in a malarious district; and various other novel and interesting deductions could be drawn from the same style of logic.

We are informed by your correspondent that he has examined a number of individuals, some healthy and some having chorea, and finds "no preponderance of astigmatism, myopia, or hypermetropia in either class." Dr. Hamilton, at the meeting of the Academy of Medicine, June 15th, assured its members that he had found that *strabismus* was a *common* associate of chorea; and I do not understand him to withdraw or modify that assertion; but Professor Donders, in his incomparable work on refractions, lays down these two propositions:

"1st. Strabismus convergens almost always depends upon hypermetropia.

"2d. Strabismus divergens is usually the result of myopia."

Now how does it happen that in a class of cases in which the gentleman acknowledges strabismus to be a common and characteristic feature, he still finds "no preponderance" of refractive errors in this class?

Your correspondent adds: "That the muscles of accommodation . . . . may become the seat of spasm *after the disease is established*, I have no doubt," and that we may obtain a more complete estimate of his views upon this subject, I quote from the report of the meeting already mentioned, as found in THE RECORD of August 12th: "Dr. H. continued by saying that his attention had been called to hypermetropia, and other eye symptoms in cases of chorea, and he had invariably found that *they were secondary*."

Dr. Hamilton must pardon those who have even moderate acquaintance with affections of the eye, if they accept, with exceedingly liberal discount, the results of examinations in refraction, made by a gentleman who vainly imagines that hypermetropia and astigmatism are *secondary* to nervous diseases, or the result of *spasm*. These, with rare exceptions, and those exceptions not the result of nervous affections by any means, are *congenital conditions*.

The suggestion that the cases of chorea "were examined after the appearance of chorea," and that "had they been examined *before*, no one would have been more ready to be convinced than himself," is quite as original and valuable as that of the Irish medicine man, who assured his hearers that if they would rub a little of his opodeldoc upon their shins just before falling down, they would be sure not to be hurt.

A single point in this communication remains to be noticed. The Doctor says: "If this is a fact (that chorea and some other nervous affections are due to refractive lesions), it is about time for neurologists to buy green spectacles, or else renounce their specialty." Whether this is a legitimate conclusion, my own investigations in that direction will not perhaps enable me to judge, but if a member of a different branch of our great profession may be allowed to make a suggestion in the matter, it would be that our neurological friends, divesting themselves of all darkling glasses of prejudice, should investigate this important subject by the pure, unclouded, and uncolored light of science and of truth.

It is scarcely probable that the truth or fallacy of the doctrine I have advanced will be established by these epistolary communications, and I intend no disrespect to the author of the communication which I have noticed, in stating that I should probably not have been tempted to this reply but for the opportunity afforded of making a suggestion which I deem of much importance in respect to examinations of eyes in this class of patients. There seems to be a prevailing impression among many ophthalmic surgeons that the presence or absence of hypermetropia can always be established by the use of the ophthalmoscope, even when the accommodation of the patient is under no restrictions from mydriatics. This impression, I am convinced, is not well founded. Nearly every ophthalmic surgeon will probably claim for himself the ability completely to relax his own accommodation when using the ophthalmoscope. There are good reasons for believing that some who claim this ability are laboring under a mistake; but independent of this, even if all surgeons possessed this power, all patients do not. So long, then, as we cannot be sure that the accommodation of the patient is fully relaxed, the absence of hypermetropia cannot be determined, especially in young persons, unless indeed the reverse condition be found; and even in some cases of apparent myopia, hypermetropia actually exists. Prof. Donders says: "Without producing paralysis of accommodation, we are never perfectly sure that we determine the refraction in the condition of rest."

In my own experience I find this proposition is especially true in respect to children and youth. Young persons who, without the use of atropine, present an apparently perfect state of the refraction, will often exhibit, after atropine has been used, a hypermetropia of 1-24, of 1-20, or even of a higher grade. Hence the importance of using atropine in all cases of chorea where the evidences of refractive errors without its use appear to be negative.

I think it but right to say that a series of examinations in this class of cases in which negative results are found, and in which atropine has not been used, is entirely unreliable.

GEO. T. STEVENS.

ALBANY, September 18, 1876.

METROPOLITAN PRACTITIONERS AT WATERING-PLACES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—It has been my desire to avoid the disagreeable necessity for entering upon a personal explanation in a public journal, but the tenor of your editorial, in your last issue, on the subject of "Hotel Physicians and Rural Practitioners," is such as to demand some additional notice of the matter. M. C. E.'s charges are of too serious a character to be passed over so lightly.

With regard to the question of the propriety or necessity for the appearance of "metropolitan practitioners" at watering-places, I do not care to trespass on your space by entering upon its discussion, except to say that all prominent physicians who spend a season at a watering-place bring a very considerable amount of custom with them—their own patients and those commended to them by medical acquaintances; they have a right also, as you concede in your editorial, to accept any other patients who may wish their services. The former is their *principal* source of profit, at all events, so far as my experience goes. My experience in hotel practice in other places is limited; but from my knowledge of the character and standing of those physicians who, as I hear, put up signs

at watering-places, of which I do not approve, and which is not done at Saratoga, I cannot help thinking that you are too sweeping in your comments on their practices. You probably have in view some exceptional case or cases. It may not be out of place to state here that the only man who, in the knowledge of the writer, is generally talked of and admitted to be a "hotel physician" is M. C. E. himself.

As regards my personal connection with this matter, let us come to the point at once. M. C. E. charges *general* dishonorable and dishonest conduct against the three or four physicians who are known to be located at the principal hotels in Saratoga. Then he charges specific unprofessional acts. There are so few of us to whom these charges could refer, and the fact is so well known, at least to the profession of New York, that we feel as if any attempt to conceal our names would be mere affectation. In fact, M. C. E. stated publicly that the *specific* charges referred to me, and that he could prove them. Learning this, I went immediately to his office, and asked him for his proof. He first refused to admit the authorship of the article; then my right to "take it to" myself. He then *denied* having said to Dr. Janvrin that I had requested permission at the hotel to put up a sign. But Dr. J. is positive on this point. He then said he *had been told* that my card had been *found under the door* of a patient then under the charge of a resident physician. This is almost too absurd for any one to notice. If the card *was* found, it could only have been placed there by one interested in injuring me, or in bringing discredit on all of us. I leave it to you and your readers to draw your own inference as to the real author of this low trick. As to sending "circulars" he could only ask, "Did not a notice of you appear in the *Medical News and Library?*" referring to a friendly notice, by the editor, of my removal to Florida. I then denounced his whole article as "false," so far as it referred to me, and "devoid of any foundation whatever," and demanded whether he would make any reparation, or would compel me to take the matter in my own hands. On the day after, I wrote him a note to the same effect, in order to put our conversation on record, and handed it to him at his office.

A further reason for noticing this article personally is that it was put bodily in the Saratoga paper having the largest circulation, and also circulated to a certain extent about the village and the hotels, or its contents made known, to the presumed benefit of its author and his worthy coadjutors, and to the corresponding injury of the metropolitans. So far as the charges may refer to Drs. Janvrin and Burchard, I am requested by them to give an unqualified denial.

Respectfully yours,

F. D. Lente, M.D.

Medical Items and News.

American Otological Society.—The ninth annual meeting of the American Otological Society was held Sept. 15th, at Chickering Hall, New York City. Dr. Roosa declined re-election as President, and the following officers for the ensuing year were elected: *President*, Dr. C. J. Blake, Boston; *Vice-President*, Dr. A. H. Buck, N. Y. City; *Secretary and Treasurer*, Dr. J. Orne Green, of Boston; *Committee on Publication*, Drs. Blake, Green, and Prout; *Committee on Progress of Otology*, Drs. Spencer and Sexton. The session then adjourned *sine die*.

The International Otological Society convened at the adjournment of the American Society. A constitution for the government of the organization was adopted, after which the following officers were elected: *President*, Dr. D. B. St. John Roosa, N. Y. City; *1st Vice-President*, Dr. E. L. Holmes, of Chicago, Ill.; *2d Vice-President*, Dr. A. H. Buck, N. Y. City; *Secretary and Treasurer*, Dr. J. S. Prout, of Brooklyn, N. Y.; *Corresponding and Assistant Secretary*, Dr. C. J. Kipp, of Newark, N. J.; *Committee on Publication*, Drs. Mathewson and Rushmore, of Brooklyn, with the two Secretaries.

A number of papers on various subjects connected with otology were then read and referred to the Publication Committee. The Society finally adjourned to meet in 1880, at the place of meeting of the International Ophthalmological Congress. A committee, composed of Professors A. Politzer, S. Moos, and R. Voltolini, and Dr. N. Löwenberg, was appointed to make the necessary arrangements for the meeting.

Hospital for Incurables in Paris.—Madame Hagelle, of Paris, has given ten million of francs to found a hospital for incurables at Paris. This will give a worthy object a good start, and perhaps anticipate a similar movement in this city, provided a medical man who has made the cure of these diseases a specialty can be secured to take charge of the institution.

Splenotomy.—M. Péan recently presented to the Académie de Médecine two patients upon whom he had successfully performed the operation of splenotomy. One of the cases was operated on in 1867, and subsequently presented to the Academy in good health. The second case, which had just recovered, was a married woman aged twenty-four years. A splenic tumor had been growing, until at the end of eighteen months after its first appearance, when it filled the entire abdominal cavity, descending into the pelvic, and even to the right iliac fossa. Various symptoms, apparently secondary to the tumor, distressed her, and abdominal pain was constant. Yielding to the importunities of the patient, M. Péan excised the spleen on the 25th of last April. The London *Lancet* (Aug. 26th) thus describes the details of the operation:

"An incision was made along the linea alba from three inches above the umbilicus to two and a half above the pubes, and a corresponding incision was made through the peritoneum. The tumor was covered by the omentum; this was removed from below upwards and pushed to the right of the tumor, beneath the right hypochondrium, and both it and the intestines were kept back by sponges and warm napkins. The tumor had the characteristic reddish-violet color of the spleen. It was seized at its lower extremity and gradually raised within the lips of the wound until it rested on the hands of the assistants who were keeping back the intestines. No other organ escaped. The gastro-splenic omentum was about three-quarters of an inch wide at the level of the hilus; it contained blood-vessels and enormous lymphatics. One splenic vein was the size of the index finger. A wire ligature was passed around the whole pedicle, great care being taken to avoid the pancreas. The pedicle was then surrounded by sponges and the spleen separated from the hilus by a single cut, being at the same time turned quickly outwards. About a quart of blood escaped in a jet from the spleen, but none fell into the abdomen; otherwise not more than thirty grammes of blood were estimated to be lost. No adhesions were met with. The sponges were removed, the great omentum spread out over the intestines, and

the abdomen closed, the pedicle being retained between the lips of the wound. The progress of the patient was excellent. The febrile reaction was slight. Some blood appeared in the urine on the third day, but diminished and disappeared a few days later. The pedicle separated in a week. The patient's spirits were very good. Eighteen days after the operation she sat up, and a week afterwards returned home."

Although this operation is a brilliant one, it must still be regarded as hazardous in the extreme, and almost under the ban of absolute prohibition.

Retiring Pension of English Army Surgeons.—There is the same difference of value placed upon the services of a combatant officer in the English army, as compared with those of the medical officers, which exists in this country. The *Lancet* says: "Now in the case of the combatant officer who is younger on entering the service than the medical officer, and has his profession to learn instead of having acquired it, the retiring pension is £200 per annum, the commuted value of which, at the age of the retiring officer, at the rate of 5 per cent., is £2,648, while in the case of the medical officer who has served for ten years, or half the time, it is only £1,000—and yet some medical men are anxious to become army surgeons.

The Russian Red Cross Society have so actively interested themselves in the care of the Servian wounded that it has become necessary for the present to stop the movement of ambulance corps from Russia to the seat of war.

Livingstone.—A statue of Dr. Livingstone, the African traveller, has been erected in Edinburgh by the side of the one of Sir Walter Scott. As they stand they are singular company for each other, both benefactors to posterity, and both joining romance and reality from diametrically opposite standpoints.

Dr. Gurdon Buck.—We are gratified to learn that the health of this distinguished surgeon is so far improved that he is enabled to walk about his room and occasionally to enjoy a drive. At present he is availing himself of a change of air in the country. He has the best wishes and warmest congratulations of a host of friends.

Population of France and England. — France takes three hundred and thirty-four years to double her population, while the same effect is worked in England in sixty-three years.

The Heat in India during the past season is reported to have been extraordinarily intense, having ranged over 100° F. for several successive days, scarcely falling at all during the night.

The Study of Mental Diseases in France.—A chair of mental alienation and diseases of the nervous system is to be created in the Faculty of Medicine in Paris.

Muzzling Dogs.—The Parisian authorities, believing that the muzzling of dogs, especially during hot weather, is one of the surest means of inducing hydrophobia, have abandoned the practice.

The Hygiene of Ruralizing.—A writer in The *Sanitary Record* (London), says: Not long ago a traveller in Jura, constrained by professional avocations to visit a sparsely populated portion of the island, found himself applying to a shepherd for a night's lodging. At earliest dawn he was aroused from his slumbers and called to the other room, when, with many apologies, "the gude wife" informed him that the hens required his bed to lay in, for that otherwise the eggs would be lost on the moor." If our friend had stayed to breakfast he could have assured himself that at least his eggs were fresh.

At a stated meeting of the Medical Society for the County of New York, held September 25, 1876, it was voted to grant certificates of membership to the following gentlemen: Drs. E. L. Partridge, E. J. Birmingham, and T. H. Skinner.

Introductory Lectures.—The opening address for the regular winter session of the College of Physicians and Surgeons will be delivered by Prof. Francis Delafield, on Monday evening, Oct. 2, 1876, at 8 o'clock.

The introductory lecture for the winter session of 1876-77 of the Medical Department of the University of the City of New York was delivered on Tuesday, Sept. 26, 1876, at 8 o'clock P.M., by Prof. J. W. S. Arnold. *Subject:* "The Teachings of Modern Physiology."

The Death of Dr. D. Brainerd Hunt.—The profession of this city has met with an inestimable loss in the death of one of the most promising among its younger members. Dr. Hunt was in every respect a well-educated gentleman. Graduating with honors at Princeton in 1866, he studied medicine at the College of Physicians and Surgeons, graduating from that institution in 1870, being the valedictorian of his class. He then spent three years abroad in hospital study, and at Berlin, Vienna, and Breslau availed himself of the best advantages.

He was an expert in pathology, and with microscopical studies generally, but devoted himself especially to the study of uterine diseases. In the latter department he rendered us valuable aid in the review department, and was up to the time of his death one of our most trustworthy counsellors in his specialty. Modest and retiring in his habits, he was an earnest and conscientious worker, a model Christian gentleman, and will be missed wherever skill, courtesy, and character are estimated. His death was the result of the lodgment of a plum-pit in the appendix vermiformis, causing perforation and peritonitis.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending September 23, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Sept. 17th to Sept. 23d, 1876.

Semig, B. G., Asst. Surgeon. Assigned to duty with Company "G," 1st Cavalry, near Soledad Station, Cal. S. O. 127, Div. of the Pacific and Dept. of California, Sept. 9, 1876.

Worthington, J. C., Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Whipple, A. T. S. O. 108, c. s., Dept. of Arizona.

Rosson, R. L., Asst. Surgeon. Assigned to temporary duty at Camp Grant, A. T. S. O. 108, Dept. of Arizona, Sept. 5, 1876.

Original Lectures.

LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

LECTURE II.

MORBID ANATOMY OF TYPHOID FEVER (CONTINUED)—INTESTINAL LESIONS—ETIOLOGY.

GENTLEMEN:—At my last lecture I completed the history of those parenchymatous changes which are most frequently met with in typhoid fever. I mentioned that these changes could not be regarded as characteristic of this type of fever, for they are present in other diseases. I also stated that by some these degenerations are regarded as the necessary result of a prolonged high temperature, but they are in no way different from those degenerations which occur as the result of blood-poisoning where prolonged high temperature does not occur. Especially is this the case in those diseases which are marked by their malignity rather than by their high temperature, as for instance, acute yellow atrophy of the liver.

Continuing the history of the morbid anatomy of this fever, we now come to those changes which occur in the lymphatic system of the intestinal track—the *intestinal lesion*. These are the most important pathological lesions, and have been called the characteristic lesions of the disease, as these intestinal changes distinguish this fever from all other forms of acute disease.

As the poison of small-pox manifests itself by certain changes in the tegumentary investment of the body, and the poison of epidemic cerebro-spinal meningitis by the formation of pus in the meshes of the pia mater, so the poison of typhoid fever acts directly upon the mucous membrane of the small intestine, giving rise to a catarrhal inflammation accompanied by changes in its anatomical structure, which, in the order of their development, are characteristic of the disease. The character and extent of these changes depend upon the duration of the fever and their nearness to the ileo-cæcal valves; the changes are most marked in the patches nearest to the valves, and less marked in those farthest removed from these valves.

In describing these intestinal lesions, I will suppose that we are examining a severe well developed case, which runs its regular course without complication. These cases can be most conveniently studied by *first* considering those which occur within the first week of the disease; then, those which are developed within the second week; next, those which are most commonly found in the third week; then those which occur within the fourth week. They appear to begin as a catarrhal inflammation of the mucous membrane. During the *first week* the mucous membrane surrounding the glands, especially that surrounding the Peyerian patches, becomes hyperæmic and swollen; gradually the glands become more and more elevated, their surface assumes a dark reddish color, interlaced by white lines; this is known as the shaven-beard appearance. These changes begin and are most marked in the glands nearest the ileo cæcal valve; they are generally well marked within forty-eight hours after the commencement of the disease, but are not fully developed until the end of the first week. By the end of the first week all the glands are involved which are likely to undergo change.

In the *second week*, the mucous membrane of the intestine becomes less red; the agminated and the solitary glands more elevated; the white lines upon their surface disappear, and they assume a uniformly red color. An unusually rapid cell development takes place in the follicles. By this excessive development and the multiplication of the cell elements of this gland structure, the follicles become swollen in all directions. Usually, the new cell growth extends beyond the limit of the follicles, so that the adjoining mucous membrane is also infiltrated with cells. These newly formed cells may wander through the muscular coat and penetrate the sub-serous tissue. By the middle or latter part of the second week the process passes into its second stage, and necrotic processes are established in the newly formed tissue. This process may terminate in two ways. First, the new elements in these ductless glands may become disintegrated and undergo absorption, and in this way they may gradually undergo resolution. Second, individual follicles of the agminated glands may rupture and discharge their contents into the intestine. Third, the most frequent and characteristic termination of this typhoid process is the separation of the dead tissue as a slough, and the formation of the typhoid ulcer. Usually the sloughing and removal of the necrotic tissue does not take place until the *third week* of the disease. The surface of the ulcers now present a yellow appearance, simply because the tissue has been stained yellow by the bile. As the sloughs gradually loosen and fall off there is a loss of substance which extends to the deeper layer of the mucous membrane, removing the entire gland and the mucous tissue surrounding it, laying bare the muscular coat of the intestine; or the necrotic process may extend and involve the muscular tissue and end in perforation of the peritoneal covering.

The size and form of the ulceration corresponds to that of the necrotic tissue; if an entire Peyerian patch is necrotic, an elliptical ulcer is formed with its long axis corresponding to that of the intestine. In the jejunum and large intestines the ulcers are usually small and round. The edges of the ulcer are sharp, tumid, and overhang the floor of the ulcer. Sometimes the ulcers are hemorrhagic.

In the *fourth week* the process of cicatrization is commenced. Gradually the swollen edges of the ulcers subside, granulation tissue springs up from their base, connective-tissue membrane is formed, the edges of the ulcers become united at their base, which is covered with a layer of epithelium. The gland structure is never regenerated. The cicatrix which is formed by the healing of these ulcers is slightly depressed and less vascular than the surrounding mucous membrane. During the healing process the cicatrix becomes more or less pigmented; these pigmented scars may be recognized years after the cicatrization has taken place. These cicatrices seldom cause any puckering or diminution in the calibre of the intestine. In many cases the process of cicatrization does not pursue this regular course; while one portion of the ulcer is cicatrized, the process of ulceration in another part may be extending; such long-continued ulceration may prolong convalescence and even cause death.

I will now briefly review these intestinal changes, and if you will bear in mind the weekly order in which they occur, you will better remember them.

The first thing noticed is congestion, which is most marked around the glands; with this congestion the

glands become changed in color. Next, the glands become enlarged, which enlargement is due to a rapid development of cells within their structure: these cells are for the most part lymphoid; but in addition there are present large round cells with several nuclei. These large round cells are formed not only in the glands, but in the mucous and sub-mucous tissue adjacent to them; consequently, the enlargement encroaches more or less upon the surrounding mucous membrane. These newly formed cells not only swell the glands and press upon each other, but they press upon the capillary vessels which furnish these structures with nutrition; consequently, there is an interference of the circulation of the gland structure, and as a result the glands become more or less anæmic; degenerative changes occur as the result of impaired nutrition.

In some of the enlarged glands the new elements become disintegrated and are absorbed, and the process ends in resolution; in others, individual follicles soften, break down, and their contents are discharged into the intestinal canal, and the patches acquire a reticulated appearance. More frequently, a necrotic process is established which causes the removal of the entire gland and its contents, leaving an ulcer with everted and perhaps overhanging edges, with the muscular coat of the intestine for its base. It is now ready for the cicatrization process, and if it progresses regularly, first the edge of the ulcer becomes inverted, then the base of the ulcer is covered with new connective-tissue cells, the edges become adherent to it, new connective-tissue cells are thrown out upon the edges, the formation of new tissue goes on increasing until finally a process of repair is complete. These ulcers do not always run such a regular course and terminate thus favorably. If the nutrition of the glands and the surrounding tissues is so interfered with that a gangrenous ulceration is established, sloughing follows, and the gland, with the muscular and other tissues in the neighborhood of the ulcers which are the seat of cellular infiltration, is removed. In some instances the necrotic process continues to extend and involves the peritoneum, causing perforation of the intestines and a fatal peritonitis. These ulcers may assume a hæmorrhagic character, with a surface of a dark color. Under these circumstances they are frequently the seat of profuse hemorrhages, which may destroy the life of the patient. Usually, when such accidents occur, vessels of considerable size are involved in the ulcerative process. Whenever the sloughing process is arrested, repair takes place in the manner already described.

As I have stated, these ulcers may be developed in the jejunum, the ileum, and the large intestines. In the lower part of the ileum, at the ileocæcal valve, they are usually of large size—so large that only small portions of healthy mucous membrane are left between them; in the jejunum and large intestines they are usually round and of small size.

Mesenteric Glands.—Associated with these intestinal changes, analogous changes take place in the mesenteric glands. These mesenteric changes are also most marked in the glands situated nearest the ileocæcal valve; they are secondary to the changes in the intestinal glands, and are usually effected in a degree corresponding to the extent of the intestinal lesions. The glands are first contested, then there is a production of lymphoid and large cells similar to those which are found in the enlarged intestinal follicles, the glands become enlarged, and are the seat of an acute cellular hyperplasia. When the enlargement has attained its full size, the hyperæmia diminishes, and the cellular elements begin to disintegrate and are absorbed. In about one-half the cases the enlargement reaches its maximum size by the middle of the second or at the commencement of the third week. The enlarged glands vary in size from that of a hazelnut to a small hen's egg. In the stage of retrogression some of the glands simply shrink and return to their normal condition; in other glands partial softening takes place and afterwards absorption, leaving a fibrous cicatrix. If the glands reach a very large size, absorption is incomplete, and dry, yellow, cheesy masses are left, in which after a time salts of lime are deposited and they become enclosed in a fibrous capsule. In rare instances the glands become fluid, their capsules are destroyed, and the softened masses escape into the peritoneal cavity and cause peritonitis.

A calcareous condition of the mesenteric glands, like the pigmented cicatrices of the solitary and agminated glands, gives evidence of a previous severe attack of typhoid fever. There is yet another pathological lesion of typhoid fever occurring during convalescence, concerning which I will speak—that is, a suppurative inflammation in the cellular tissue upon the surface of the body. The inflammation is not of an active type, but is accompanied by some redness and pain; gradually a tumor is formed at the seat of the inflammation, usually this occurs where there is the greatest amount of pressure. After a time fluctuation becomes distinct, the swelling increases; sometimes two or more of these swellings coalesce, and finally an immense abscess may be formed, which when opened will discharge a pint or more of pus. These abscesses are due to suppurative inflammation in the cellular tissue of the skin. Retro-pharyngeal ulcers are the result of suppurative inflammation of the connective tissue. As a result of imperfect nutrition of the skin, a gangrenous inflammation of the skin may be developed, which gives rise to "bed sores," as they are commonly called. These are especially liable to occur in the latter stages of typhoid fever which has been attended by a prolonged high temperature. The slough may form over the trochanters, over the sacrum, or wherever the tissues have been subjected to pressure for a long time, and is a consequence of impaired nutrition of the skin. Sometimes this gangrenous process not only involves the skin, but also the subjacent cellular tissue and the muscles. Gangrene of the toes and portions of the integument which are not subjected to pressure, is due either to thrombosis or embolism.

This completes the history of the anatomical lesions of typhoid fever. In connection with this history I would call your attention to something of special importance, which I wish you would be careful to remember, namely: that typhoid fever is a specific disease; that it has a specific pathological lesion, a catarrhal inflammation of the intestinal mucous membrane, attended by special follicular changes; and though you may find present in other diseases the changes which I have described as the characteristic lesion of typhoid fever, yet there is no other disease in which they have a regular development in which the different stages can be indicated with a degree of certainty by days and weeks.

Etiology.—We very naturally pass from the consideration of the morbid anatomy of typhoid fever to its etiology. According to the classification of fevers which I have adopted, it is included in the list of miasmatic-contagious fevers. Usually, it has been regarded as an endemic form of disease. There seems to be no connection between its development and destitution; for not only does it choose its vic-

tims from the hovels of the poor, but from the dwellings of the middle classes, and from the palaces of the rich. It may occur as an isolated case, or whole households and neighborhoods may be stricken down with this disease. We must therefore regard the the causes of its production as local and limited, and not widespread. It is possible for it to prevail as an epidemic, but it must first have been endemic.

In studying the etiology of this fever, the prominent questions present themselves:

First.—Is it a contagious form of disease?

Second.—Is it ever of spontaneous origin?

The question of contagion is one that has been very thoroughly discussed. For many years representative medical men have differed upon this point. After years of careful investigation, I think it may be now unhesitatingly stated that facts do not sustain the opinion that typhoid fever is ever, strictly speaking, a contagious disease, or that it is ever directly transmitted from one individual to another.

Persons sick with this fever are now admitted into our general hospitals, and are placed in beds by the side of patients sick with pneumonia or any form of chronic disease, without endangering the lives of such patients. This fact shows how generally the profession regard this disease as non-contagious. Typhoid fever is no longer restricted by quarantine regulations. All these facts tend to dispose of the question, is it a contagious disease?

The question, is typhoid fever of spontaneous origin? has also been thoroughly discussed, and there are strong advocates on both sides of the question.

Some of those who believe that it may have a spontaneous origin maintain that the poison which gives rise to it is developed by the decomposition of organic matter, and that the specific character of the fever is due to the particular substances which arise undergoing decomposition. Others maintain that the decomposing substance is mainly human excrement, in other words, that decomposing human excrement is necessary for the production of the peculiar poison which gives rise to typhoid fever. Again, others who believe that the disease is of spontaneous origin maintain that the presence of vegetable matter in certain conditions is necessary for its production, and that these conditions are similar to those which exist when miasmatic fevers are developed, the difference in the two poisons depending rather upon the rate of temperature than upon the character of the ingredients.

There is a view only recently advanced in regard to the origin of typhoid fever, that sewer gases contain the poison which develops typhoid fever.

On the other hand, it is maintained by those who do not believe in the spontaneous origin of this fever, that in addition to decomposing animal and vegetable matter, it is necessary that the specific typhoid poison shall be incorporated in the decomposing mass. It is the leaven (if you choose so to call it) which is to leaven the whole mass. Daily observation seems to clearly prove that vegetable or animal decomposition alone is not sufficient for the development of this disease, even admitting that it depends upon the decomposition of human excrement. In how few of the many dwellings permeated with the effluvia from privies do the inmates have typhoid fever.

Again, facts do not sustain the claim of those who say that sewer gases contain the typhoid poison, for those cities in which the sewerage is most imperfect, and those houses most frequently permeated with sewer gases, are not the hotbeds of typhoid fever. Again, this fever is more prevalent in the country than in the city, in places where there are no sewer gases; indeed, well-marked cases of typhoid fever are of quite rare occurrence in the city, and when they do occur seem to be developed independent of defective sewerage. In other words, all the elements which favor its production may be present, such as animal and vegetable decomposition or sewer gases, and yet not a single case of typhoid fever be developed, until some person having typhoid fever comes within the precinct, or some substance containing the typhoid poison is brought within the boundaries favorable to its development; then a severe epidemic of the disease may be developed.

In carefully reviewing the history of the origin of this disease in the different localities in which for the first time it has suddenly appeared and prevailed, we will find that the advent of one suffering from the disease, or the introduction of matters from such a person, has been the starting-point of the epidemic; in other words, that one of these two conditions is a primary necessity for its production.

We therefore almost necessarily reach the conclusion that something is necessary for the development of typhoid poison besides favorable external conditions; that animal and vegetable decomposition does not primarily originate the poison, but furnishes a favorable soil for its growth and development.

Facts warrant us in making the statement that while on the one hand typhoid fever cannot be regarded as a strictly contagious disease, on the other hand it is not of spontaneous origin.

It is hardly necessary for me to review all the facts which have a bearing upon this subject. I believe any one who without prejudice studies them will arrive at this conclusion, that when typhoid fever makes its appearance in any locality, its development is preceded by the introduction of a specific typhus poison, which has been reproduced (in most instances) in connection with decomposing human excrement.

The question now arises, What is the real nature of that poison derived from a person sick with typhoid fever, which has the power of indefinitely reproducing itself outside of the body in connection with decomposing organic matter, and thus becomes the infecting agent, when individuals are brought within its influence?

The history of endemics of typhoid fever leads to the conclusion that the poison is contained in the fæcal discharges of the sick. When such excrement is in a fresh condition the poison is not active; it must go through a stage of development outside of the body. This may take place in the excrement itself, but it goes on more rapidly and abundantly if the excrement is collected in privies or in earth that is already saturated with organic matter. In this way you can readily explain how a typhoid fever patient coming into a locality previously free from the disease can establish there a focus of infection, from which many persons may become diseased.

It is evident that this poison is not active in its fresh state, from the fact that the disease is not carried directly from one individual to another—as, attendants, nurses and physicians are no more liable to the disease than those who in no way are exposed to the disease and live in a healthy locality. Mothers may sleep in the same bed with children who are sick with the fever without contracting the disease. As has already been stated, in order that typhoid excrement shall become effective in the transmission of the poison, it is necessary it should go through a stage of development in connection with organic matter outside of the body; so it travels from the diseased individual to the localities which are favorable to its

development, and again from these localities into the human body.

It is difficult to determine the period of incubation, or length of time the poison must remain in the body before symptoms of the disease are manifest. The history of isolated cases would lead to the conclusion that the period varies from fourteen to twenty days.

The next question that arises is, How does the typhoid poison gain admission to the human body? Undoubtedly there are two principal sources of infection, namely, the air we breathe and the water we drink. A large number of well authenticated histories have now established the fact, that this fever may be developed by gases which emanate from privies, sewers, etc., which have been the receptacle of excrement from typhoid patients, and also, by drinking water from springs and wells which have become contaminated by matters from adjoining privies and cesspools. It is also now an accepted belief, or rather is regarded as an established fact, that water remains contaminated, though far remote from the point where it came in contact with a defective sewer or water closet.

Soil pipes and sewerage may be defective for a long time, perhaps a year, or even longer, and no case of typhoid fever occur, when suddenly an endemic of typhoid fever breaks out, and careful investigation shows that its development was preceded by the introduction of the excrement of a single individual sick with the disease.

It is the belief of some that milk can convey the typhoid poison, and there is evidence in favor of this opinion; but I think there is stronger evidence that the water in the milk and not the milk itself, is the medium through which the poison is transmitted.

This poison has great vitality. Typhoid fever frequently occurs in the same locality year after year, when the surrounding conditions are favorable to its development. Those conditions which favor its development are more frequently present in the autumn than at any other season of the year, and for this reason it has been called Autumnal fever.

Usually it makes its appearance in a locality, year after year, at about the same time; case after case is developed until entire households and neighborhoods become its victims. Individuals who come to care for the sick may contract the disease, and even persons who visit houses in which the disease is prevailing may afterwards develop the fever, contracting it, not from the sick, but from the infected atmosphere of the locality.

Age must be regarded as a predisposing cause of typhoid fever. It is much more likely to occur in young than in old persons; it occurs most frequently between the ages of fifteen and twenty-five, and is rarely met with in persons over fifty.

There are also individual idiosyncrasies which seem to predispose to this fever. Some contract it upon the slightest exposure to the influence of the poison, while others, frequently brought in contact with it through long endemics, escape. Again, an individual may have repeated attacks of typhoid fever. I have in mind a physician who had typhoid fever four times, the last attack proving fatal. A person who has had typhus or scarlet fever is not likely to have a second attack, but no such immunity follows an attack of typhoid fever. Whatever view we take of the exact nature of the typhoid poison, it has been quite conclusively demonstrated that the typhoid poison differs very essentially from that of other fevers.

From this brief review of the etiology of this fever, we are led to the following conclusions:

First.—That its development is independent of over-crowding, and that it attacks the rich and poor indiscriminately.

Second.—That it may be communicated from one person to another through the excrements which have undergone decomposition after their discharge.

Third.—That an endemic of typhoid fever only occurs where the air or drinking water of the locality has become poisoned by emanations from typhoid excrements which have undergone decomposition, and that, if the fever becomes epidemic, it is a circumscribed epidemic, and not widespread.

Fourth.—That the exact nature of the typhoid-fever poison is still unknown.

Original Communications.

NEW FACTS AND SUGGESTIONS RELATING TO HAY FEVER.

By GEORGE M. BEARD, M.D.

During the past vacation I spent some time in Bethlehem, N. H., where I saw and studied, in greater or less detail, about one hundred cases of hay fever. In the White Mountain region—including Bethlehem, Whitefield, Lancaster, Jefferson, Twin Mountain House, Fabyan House, Crawford House, Glen House, Gorham, and Bethel—there are probably five hundred hay fever refugees, most of whom stay there during the month of September. At the meeting of the U. S. Hay Fever Association there were not far from two hundred victims of the later form of the malady, or "autumnal catarrh." The chance for the careful study of this interesting disease offered in the White Mountain region at this season has no precedent in history, and I am surprised that it is not better improved by physicians. Hay fever is a malady interesting not only in itself, but its successful study requires a knowledge of many other branches of medical and other sciences, and is one of the best means of mental discipline that I know of. In regard to the general nature and philosophy of hay fever, the observations at the White Mountains added little to what I have already published in my work on the subject, but some minor details were learned that seem to be of considerable interest.

1. *The Proportion of Cases that are benefited by a Visit to the White Mountains.*—Only a small percentage of cases obtain entire relief, while nearly all—probably nine out of ten—obtain some relief. In about four cases of every five, the relief is of a very decided character. The majority of the cases have some of the symptoms off and on during their stay, but in a modified form, and the relief is a great gain, and fully pays them for their exile from home.

The chances of relief appear to be three or four times greater than at any of our sea-side resorts. Different places act differently with different cases and in different years. In some cases the relief is immediate, in others gradual. Those who come in the latter class sometimes get disheartened on arriving at their destination; their symptoms hang on for a few days perhaps, and in despair they go to some other town in the White Mountain region, perhaps but a few miles away, and soon recover. They judge that the place last visited is better than the first one. This conclusion is oftentimes a mistaken one; they

might have been relieved if they had stayed where they first came.

2. *Other Places of Relief.*—Next to the White Mountains, I would rank the Adirondacks, and in the western country Marquette and Mackinaw. The Catskills are uncertain for the average, but for some cases answer very well.

There seems to be no island on our coast sufficiently far from land, and sufficiently barren to be a trustworthy resort for all, or even for the majority of cases. Land breezes are sure to bring distress.

While at Bethlehem, a young man was brought from Block Island, in terrible distress from hay fever. He had been made worse there. One gentleman, who had had the hay fever almost everywhere in Europe and America, said that he never suffered more than on Nantucket. Martha's Vineyard relieves some; so also do the Isles of Shoals and Fire Island; but if one must leave home, it is better to go to a place where there are three chances out of four of being greatly relieved, than to places where the chances of such relief are but one out of four.

A sea voyage is sure to relieve, and almost always speedily. I have record of but one case where the symptoms lasted long after embarkation.

Travel in Europe usually gives exemption, but not in every case. One gentleman told me that he had the later form of hay fever in St. Petersburg, in Vienna, and in Liverpool. Several have had it slightly in Paris.

3. *Why Relief Regions relieve.*—To answer this question, I must briefly explain the philosophy of hay fever. For the past half century and more, physicians, and scientists, and sufferers have been looking for an *objective* cause of this disorder. They have studied hay, and grass, and flowers, and fruit, and the pollen of ragweed and corn, sunlight, and dust of every form, and when *any one* of these substances has been found to excite the symptoms in *any single case*, straightway the problem has been believed to be solved. An excellent illustration of this one-sided method of studying disease is found in the monograph of Blackley, of England, who, by a series of careful and admirably carried out observations, proved, what was well known before, that the pollen of certain grasses may in some cases excite the paroxysms, and hence concluded that in this single and simple fact was the whole philosophy of the disease, and that it should be called "pollen catarrh." Consistently with this line of reasoning and the habit of looking at one side rather than all sides of a complex subject, observers in this country have proved that ragweed and the pollen of corn excite the paroxysms, and term the disease "ragweed fever." Others find that the paroxysms are excited by peaches, and call it "peach cold;" others still by snow, and call it "snow cold."

All of these observers are right and all are wrong. In reality hay fever, whenever and wherever occurring, is a *subjective* disease; it is from within, not from without, and all these excitants, whose name is infinity, are but what friction is to a match. The tendency to the disease is a nervous one, and is innate; no disease is more hereditary than this. I have statistics of fifty-four cases in twelve families. I have notes of twenty-five cases, that had the disease from infancy. In Newport there is a man who has it, whose father and grandfather also were sufferers; at Bethlehem I presented to the Association a child, five months old, with all the symptoms of hay fever, inherited from its mother.

Carrying out the illustration of lighting a match, we may say that the tendency to hay fever may remain latent for a long lifetime, until, under the irritation of some excitant, it suddenly blazes forth. Thus at Bethlehem there was a man who was first attacked at the age of sixty, on removing from the West to Rhode Island; and another case of a man whose first attack was on exposure to ragweed and tomatoes at the age of sixty-five. A father and a son were first attacked at *the same time* while on a visit at a certain place in New Hampshire; thus demonstrating the relation of the latent tendency to the exciting causes, and also the hereditary character of the malady. All of these exciting causes, dust, hay, dried and fresh, pollen of all kinds, sunlight, gaslight, foul air, smoke, cinders, mental influence, peaches, strawberries, ipecac, etc., etc., our ancestors in the last century were exposed to as much as we now are; but they did not in them excite hay fever in any of its forms; and even now not more than one out of five hundred or a thousand of our population are affected. *None of these excitants can produce hay fever unless they find the nervous system prepared for them.*

Regions like the White Mountains, give relief for these reasons:

1. *Coolness of the Air.*—Heat is one of the most important of the many exciting causes; for this reason, as well as for the greater prevalence of vegetable irritants, hay fever is more common and more persistent in the summer than in the winter.

2. *Dryness of the Air.*—Moist air, as we all know, is more oppressive than dry air at the same temperature, as is well shown in a comparison of the Turkish and Russian baths. Then, again, moisture in the atmosphere holds in solution and mechanically sustains various irritants more than dry air. I suspect that dust, when raised, does not remain in the air in that region as in other districts.

3. *Comparative Freedom from some of the worst Vegetable Irritants.*—Ragweed* does not grow in these regions to any great extent; and there is no great amount of corn, and for miles and miles in every direction extend immense forests.† Mr. Blackley has shown that pollen can be carried for long distances and at great heights in the air. Therefore a very large forest anywhere should be a good refuge for hay fever sufferers. Hay and flowers are raised in the White Mountains, and those who visit that region for the early form, or rose cold, may be disturbed thereby. "Golden-rod" also abounds in the mountains, and now and then a patient is annoyed by it. But of all the excitants dust is the most universal, and this summer being dry, has been a hard one for the sufferers who have been obliged to forego the pleasure of riding out. The general *tonic* effects of mountain air—the result of the coolness, the dryness, the rarification and diminished oxidation, as well as of the ozone and electricity—are also of value in hay fever.

Europe relieves the majority of American sufferers, partly because our "dog days"—a powerful exciting cause—are not known there, and partly from the absence of "ragweed" or corn.

The ocean air always relieves, because it is always cool, bracing, and sedative, and is entirely free from vegetable irritants and dust.

"Exempt" is, I am persuaded, too strong a word to apply to the White Mountain district, Adirondacks, Marquette, etc.; for hay fever may persist even after visiting those sections. There is also evidence that in

* Otherwise called "black weed," "Roman wormwood," *ambrosia artemisiæfolia*, and "sneeze weed."

† The vegetable irritants that are most likely to excite hay fever symptoms are not found in forests, but accompany cultivation.

the White Mountains, even in the heart of the so-called "exempt" region, hay fever may be rarely indigenous. Two indigenous cases are reported to me at Bethlehem, but I have not yet fully investigated them.

Elevation alone does not bring even relief. At Idaho Springs, Colorado, seven thousand feet above the level of the sea, there is a man who has suffered every year for ten years. In that region, alkali dust appeared to be an exciting cause. So far as I can learn there is no part of the country, except California, that is free from hay fever, although it is less common South than North.

4. *Winter Forms of Hay Fever.* — I have elsewhere shown that hay fever may arise at any season of the year, and is not at all peculiar to summer or autumn, although it is more frequent or more persistent at these seasons, partly on account of the heat, and partly on account of the greater abundance of vegetable and other irritants in the air.

A number of cases have been reported to me, in which the symptoms are brought on by the presence of *snow on the ground*, or by melting snow, or by cold winter winds. I saw a number of cases of this kind at the White Mountains. One lady, a pitiable sufferer from the later form of hay fever, told me that one winter evening, on riding a short distance over the snow, all the characteristic symptoms came upon her. In cases of this kind, the peculiar cold of the snow must act as an irritation. Melting snow is quite a common excitant. Snow in its various relations is so frequent an excitant in the winter, that the term "snow fever" might be used as appropriately as "hay fever," or "rose cold," or "peach cold."

One sufferer, a country physician, tells me that he cannot curry his horse at any season of the year without exciting the paroxysms. A young lady declares that a breath of air at any time may start the symptoms. A young lady, sixteen years of age, cannot stroke a cat in her lap without suffering; her father, whom I know well, is a hay-fever victim. One lady, who every autumn has the "catarrh," never gets fully well before April. Hay fever, therefore, must be regarded as a disease that exists all the year round; and on the nerve theory it ought to do so. In one of my cases the *first* attack was in winter, being excited by the presence of some flowers.

5. *New Symptoms.*—In regard to the symptomatology of hay fever, it would seem that little could be added to what is already known. In my work a case is noted in which there are no nasal symptoms, but instead a painful eruption (probably eczema) on the face, coming on regularly at the hay fever period. The late Dr. Wm. C. Roberts speaks of coldness at the end of the nose as one of his symptoms. A reviewer in the New York *Sun* mentions pain in the back of the neck and head as a part of his personal experience. At Bethlehem I saw a lady who usually has the asthma badly, but this season is troubled with what appears to be spasm of the œsophagus, making it difficult to swallow. Another case of like character was reported to me, but I did not see it.

I have already shown that Dr. Wyman is in error in making any distinction between the symptoms of the different forms of hay fever. The symptoms of one form are the symptoms of all forms, asthma included.

6. *Mental Influence.*—All diseases—acute and chronic, functional and organic—are more or less under the influence of the mind. There is no question that the symptoms of hay fever are to a degree subject to mental influence. Whether the malady can be excited by psychical contagion purely, is doubtful. There is as yet no evidence that the congregating of large numbers at the mountains is in any way injurious, although it may be so in some cases. The popular belief that the disease spreads because it is fashionable, because, so to speak, it "is the thing" to have it, is certainly a mistaken one. Hay fever increases as a necessary result of the operation of the law of inheritance, and on account of the increasing nervousness of the American people. It increases for the same reason that neuralgia increases.

It is possible, and indeed probable, that in some cases the exact periodicity of the attacks may be in part the result of expectation; but it is a great error to suppose that they appear as the sole result of this influence.

7. *Exciting Causes of the First Attack.*—Under this head several facts have been obtained. A lady was first attacked at the age of thirty-five, after the prostration of a confinement; that year she had the early form, or "rose cold;" the next year and subsequently she had the later forms. A lady, now residing in Stamford, Conn., was first attacked ten years ago, while eating strawberries; the peculiar itching of the mouth came on at once. It was the month of June. She now has the later form. Her symptoms were once excited by *syringa* in the hair of a lady in the room, although she was not aware of its presence. At one time she was attacked while eating a raspberry pie; it seemed that a few strawberries had been accidentally mixed up with the raspberries.

In a young man the first attack appeared on getting his feet wet. In one case the symptoms first appeared when exposed to peaches in a garden; the patient was forty-five years old. In two cases the first attack appeared while exposed to dust, riding on a stage-coach.

8. *Effect of Long Exemption.*—Exemption from the attacks, even when absolute and prolonged for many years, does not always cure. I was told of a man who resided abroad twenty-two years, and all that time was free. On returning to New York he was attacked shortly after landing.* He became vexed, and took the next steamer to Europe. One Baltimore lady was exempt five years while residing in Cuba, but was not cured of the tendency to the disease.

Some think that the general health is improved by long exemption; this is usually the case with those who are weakened by the attacks. It should be noted, however, that all persons are not weakened by the attacks of hay fever, even though they are violent; as soon as the symptoms cease they feel as well as before. In hay fever also, as in sick headache, the attack may be preceded by perfect health.

9. *The Middle Form, or July Cold.*—The middle form of the disease is less common than the early (rose cold) or later form (autumnal catarrh); but I already have notes of over twenty cases. I discovered the existence of this form early in my researches. It may interchange with any of the other forms or run into the later; some have all three forms. I have received a letter from a man who, from the hour after his birth, has been a sufferer from the later form; this year, after reading a copy of my work, he was attacked about the middle of July. He raises the query whether the middle form appeared for the first time this year as a result of mental influence, or whether a piece of growing corn in a garden near by may have had something to do with it. These divisions into the early,

* While these notes were in course of preparation, a friend who has been three seasons in Europe called upon me. During his absence he was free; but on approaching Staten Island, as soon as the land breeze struck the steamer, the symptoms came on.

middle, and later forms—with the corresponding names, rose cold, July cold, and "autumnal catarrh"—are for convenience only; they indicate no special differences in the nature of the malady, which always and everywhere is the same thing. Hay fever may start any time between May and October, and may end any time between July and April. Brief attacks may begin and end at any season of the year. The symptoms of one form are the symptoms of all forms, the only difference being in the nature of the excitants. In this country the most common form is the later, beginning in August and ending usually in September, October, or November; next in order is the early form, beginning in May or June and ending usually in July, but sometimes running into the middle and later forms; last and least frequent of all, in the proportion of about ten to one, is the middle form, beginning in July and ending in August, or running into the later form. The division between these forms is far from being mathematical or absolute.

10. *Periodicity of the Attacks.*—Like all or nearly all other nervous diseases, hay fever, in all its leading forms, tends to be periodic; but only in a minority of the cases—about one out of five—does it always every year come on the same day. In the remaining cases the date of the attack is liable to be so far modified by circumstances as to vary all the way from a day or two to several days or weeks. Out of thirty-two cases of the later form in Bethlehem this year, six declared that the attacks came on always every year invariably the same day, but the day was different with persons. In twenty cases the time of the attack was liable to vary, but never varied more than five days. In six cases the variation was liable to be more than five days. Very rarely the attack comes on every year at precisely the same hour. In one of my cases it came on at eight o'clock in the morning. An intelligent sufferer tells me that the winter attacks come on in some cases just six months from the date of the summer attacks; but I have not investigated this claim.

11. *Natural Cure of the Disease.*—We have seen that hay fever is a disease with very long arms: it has one hand on the cradle and the other on the grave. The query whether the tendency to the disease is ever outgrown, therefore, becomes one of practical moment. Now and then the disease disappears spontaneously. A lady of Swampscott, Mass., had the later form for many years, but finally outgrew it. A case is reported to me of a lady, residing in New Jersey, who had the later form for twenty years; she took quinine in large doses, and now for several years she has been free. Cases are reported also where the early form is outgrown.

12. *Treatment and Verification of the Theory.*—Prevision, says Comte, is the test of a scientific theory. This test, the nerve theory of hay fever can endure, for not only does it account for and harmonize all the known phenomena of the disease, but it suggests new facts and arguments for its own verification, thus fulfilling apparently all the conditions requisite for a scientific hypothesis.

Guided by this theory, one can tell, from the detailed description of any locality, whether it is or is not a good relief region for hay-fever subjects, and also whether any remedy is likely to help any cases. If all the victims of hay fever were to enter upon a crusade to the north, they would in time all be delivered from their sufferings. A few would be relieved at the sea coast, others on the hill regions of our northern States; a still larger number at the White Mountains, Adirondacks, and the great lakes; those whom these latitudes and altitudes failed to help, would be mostly entirely free on arriving at Nova Scotia, and almost every case would be relieved before reaching the snows of Alaska or the icebergs of Greenland.

Under the guidance of this theory, one could assert that the malady does not exist, or is very rare among the native population of South America, Central America, the West Indies, and among savages everywhere is unknown.

This theory led me to recommend central and local galvanization for hay fever before it was known to have been of practical efficacy in this disorder. At the present time, the evidence in favor of this method of treatment is constantly accumulating. The same theory suggested Turkish baths, which are now known to act most pleasantly in certain cases; other nerve remedies, as gelsemin, calabar bean, chloral, and hypodermic injections of narcotics, are to be recommended on the same principle. The value of the *preliminary* use of quinine, arsenic, and other tonics was suggested by this theory before there had been positive proof that good had come from such treatment.

Accepting this theory, we must also logically accept the view that no general specific ever can be found for hay fever; and as cases differ as much as faces differ, no two are to be treated precisely alike. Each person must find his own specific by experimenting through the whole range of tonics and sedatives. Every man has his own hay fever, as he has his own sick headache or neuralgia. All these predictions were made in 1874, and on the strength of this hypothesis. Experience is confirming their soundness.

I have long observed that hay-fever patients, when the symptoms are upon them, become quite disheartened, and are averse to doing anything for themselves. This feeling of discouragement is indeed one of the symptoms of the disease. In this respect, hay fever is like sea-sickness. There is a positive basis for discouragement in the ill success that has attended the use of remedies, but it must be remembered that the experiments have been made in the wrong direction. The dominant belief has been that the disease is parasitic (Helmholtz) or infectious (it is so classed in Ziemssen's "Cyclopædia"), and the hope has been that some specific would be found for it—some single and powerful antidote for a single and powerful poison. Under the inspiration of this error, patients have treated themselves most cruelly by violent and painful processes. Those who have passed through this ordeal say that they have "tried everything;" in fact, they have tried nothing properly. In the treatment of hay fever, almost any sedative or tonic may be tested. This general rule should be kept in mind, always that nothing should be used so strong as to cause pain or unpleasant sensations of any kind. Treatment that is not followed by agreeable effects will not be likely to do good. There is a constant temptation with some to overdo everything that is tried, especially the local applications.

Dr. Carroll writes me that goggles are of service during an attack, partly by directly protecting the eyes, and partly, also, by preventing the reflex symptoms that may be excited by the action of irritants on these organs. Cotton worn over the eyes during railroad travel is a good protection.

For the relief of the nasal symptoms, I would recommend the following:

℞ Spts. camphor. . . . . ℥ ij.
Chloroform . . . . . ℥ v.
Carbolic acid . . . . . ℥ i.
Alcohol . . . . . ℥ iij.

Inhale from a vial.

In regard to the hygiene, it should be remembered

that the disease is one of debility and irritation, and needs strengthening, not weakening, influences—good and abundant food, and warm clothing. Flannel is to be used freely. Almost all the victims agree that they suffer less when they keep quiet in the house. Even in the mountains, riding about in dust brings on distress in many cases.

Progress of Medical Science.

Irritability in Different Parts of the Same Nerve.—To examine the irritability in different parts of the same nerve, Dr. K. Hällsten employed the following method of preparation: The two sciatic nerves of the frog were completely isolated by dissection from all the surrounding parts, but left in communication with the lumbar portion of the spinal medulla. On one of the extremities the nerve was divided in the popliteal fossa, while on the other the attachments of the gastrocnemius muscle to the trunk of the nerve, to the femur and to the tendo Achilles were left intact. All the other parts were removed. This preparation was placed in the myographion of Pflüger, with the precautions necessary to prevent injury of the nerves. The divided nerve was placed on two pairs of electrodes, one approximated to the central organ, the other towards the cut end.

The electrodes consisted either of two pairs of pins, soldered to copper wires, or of points of ordinary clay, non-polarizable (of DuBois-Reymond). By a special arrangement, the effects of unipolar induction, etc., were removed with certainty. In a series of experiments, some of which were made as early as 1872, the nerve was excited by induced currents, succeeding to very close intervals; in the others he employed the induction apparatus of Ruhmkorff, and the nerve was submitted to a single excitation, engendered by the induced current of rupture.

Whichever method was employed, it was ascertained that the reflex contractions in the muscle differed in extent when the excitation of the same force acted on the different parts of the trunk of the divided nerve. It was also demonstrated, by experiments, that an irritation of less considerable intensity was necessary to provoke reflex movements, when it was applied to a portion nearer the central organ than when more distant.

This result cannot be explained by the theory generally admitted—namely, that the impulse which is essential to the function of the nerve increases in force proportionally to the road travelled over. According to this theory, the results of the experiments would have been quite opposite, from which Dr. Hällsten concludes that the irritability of the sensitive nerves is different in the different parts. After having refuted another mode of explanation, which might appear probable, and recalled to mind several facts which prove that the specific irritability is not the same in the different parts of the nervous system, Dr. H. explains not only his observations on the sensitive nerves, but also those of Pflüger on the motor nerves, which have long been known, by this fact: *That the specific irritability of the motor nerves as well as of the sensitive nerves differs at different points, and that in general it decreases from the centre towards the periphery.*—*Nordiskt Medicinskt Arkiv.* 8de. Bandet, No. 5.

Belladonna Poisoning an Infant.—Dr. Horton reports the case of a boy, two and a half years of age, who swallowed forty-five grains of the extract of belladonna. When seen two hours later, almost every muscle of the body, especially those of the extremities, seemed to be in a spasmodic action. The skin in color, and to a certain extent in thickness, had the appearance of scarlet flannel; the teeth were tightly clinched, with a little froth flying out between them at each irregular spasm of the muscles of expiration; the eyelids were widely separated and fixed; the pupils were dilated to their utmost limit and immovable; the child was totally insensible, and the pulse could not be counted on account of the incessant muscular twitching. An emetic of sulphate of zinc was at once given, followed, after the vomiting had ceased, by two teaspoonfuls of tincture of opium in one dose, and two teaspoonfuls more in divided doses every half hour. Seven hours later the muscular twitching had partly ceased, but the eyes were still dilated. No further treatment was employed, and in a few days the child had recovered his usual good health.—*Medical and Surgical Reporter*, June 10, 1876.

Successful Treatment of Polyuria.—M. Hayem mentioned at the meeting of the Paris Biological Society, March 18th, 1876, the case of a man aged forty-eight, who had enjoyed good health up to 1867, when he suffered from a nervous attack, characterized by loss of consciousness and paralysis of the right arm. In 1874 the sight became impaired, but he was otherwise in good health until February, 1875, when he became affected with polyuria, polyphagia, and polydipsia, and soon after, nocturnal incontinence of urine. When the patient was first seen by M. Hayem, the face was puffed and the lower limbs œdematous. The urine contained a certain amount of sugar but no albumen: he voided about four quarts and a half of urine, containing about two ounces of urea per diem. After a treatment of twenty-eight days the patient taking about one grain of opium per diem, the quantity of urine diminished to about three pints, and the urea to about seven drachms in the twenty-four hours. The general health was much improved. It is supposed that the opium acted as an alterative to the nervous system. In similar cases Trousseau and Bouchard succeeded with valerian.—*The Lancet*, June 17th.

Infective Substances.—Dr. Stucker, of Lower Austria, proposes to divide infective substances in accordance with their place of origin into three groups, viz.:

1. Entogenous, of which syphilis is undoubtedly an example.

2. Amphigenous, as in the case of the agents which have been thought to produce diphtheritis.

3. Ectogenous, to which all those poisons, both animal and vegetable, belong, which produce simple poisoning.

This classification has no reference to the question of communicability. Its principle is quite trustworthy, because whatever advances may subsequently be made in our knowledge, all infective substances must be included in one or other of these groups. Dr. Stucker considers it advisable to call those diseases zymotic which are capable of spontaneously multiplying their causes, and to regard infective diseases as a wider class, of which zymotic diseases are only a subdivision. The animal poisons may thus be included among the infective diseases without necessarily belonging to the zymotic.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 7, 1876.

THE INFLUENCE OF THE MEDICAL PROFESSION.

THE manner in which the profession is expressing its opinion upon many of the general questions bearing upon social and sanitary reforms shows that it is beginning to appreciate its legitimate relations to the public. On the other hand, the eagerness with which the press seize upon these opinions, and give them the widest possible publicity, is an evidence that they are worthy of respectful consideration.

Hitherto, as a profession, we have kept ourselves in the background regarding the discussion of questions which affect the public good, and in which, as experts, we should have taken a part. The excuse for this neglect has been the want of appreciation of such services on behalf of the people. This, however, has a foundation more apparent than real. We have, however, no right to throw all the blame upon the public for ignoring the value of suggestions which we have been inclined to offer it, or of efforts which we have made to give them a practical turn. The people have not properly understood our motives, and have been unable to separate what they consider class interests from what we consider the public good. It must not be denied that the efforts which the profession have made in bygone days to obtain class legislation, and to protect what it was pleased to designate professional rights, has tended to create suspicion, if not distrust, of any purely professional movement. It may take considerable time before these prejudices are entirely uprooted, some time before the profession, as a body, will pardon the wilful neglect of its former counsels; but that a proper understanding is being reached, we see the most encouraging evidences. Medical men are not so reticent as formerly, and are beginning to prove to the people that they can take an interest in necessary reforms as good citizens and as experts, entirely independent of individual or class considerations.

Far from degrading itself in the eyes of the people, the profession is rising to the becoming dignity of a learned and liberal body. Its opinions are received with flattering eagerness, and are commanding deserved respect. As a body, we are taking rank with the leaders of public opinion upon every subject concerning which we are qualified to speak. In consideration of these facts it is easy to see that our influence must increase in proportion as we use the opportunities which are offered to us. The circumstances of advancing civilization, the growing importance of the science of preventive medicine, its widespread ramifications into every social and political interest, force upon us obligations which no code of ethics can ignore, and the discharge of which no false idea of professional modesty should prevent. That we are becoming equal to the emergency is one of the most promising signs of the future.

Mr. Gladstone, the English statesman, recently gave it as his opinion that, in comparison with other professions, ours is destined to become increasingly important and influential. This is an opinion which is held, not by him alone, but by public men in this and other countries; and if we can judge of the tone of the public press, and the high regard which it has of professional services in state medicine, as indicating popular sentiment, we are warranted in assuming that the opinion is well founded.

The past few months have been signalized by the meetings of associations of almost every sort; and in all of these, where the voice of the medical profession has been entitled to a hearing, the opportunities for extending its influence have not been lost. Leaving out of consideration the societies which are strictly medical in character, and in which public questions were occasionally discussed, we turn to those which are more general in scope and more strictly associated with political and social reforms. In these the medical man has made himself a prominent advocate of advanced ideas, a strenuous supporter of radical reforms, and a judicious leader of public sentiment.

The papers upon the nature and treatment of lunacy, inebriety, prostitution and kindred topics, read before secular bodies, have been of the highest order of merit; and, while they prove the fitness of the writers to handle the subjects, reflect credit upon the profession in the name of which they speak. This is as it should be, and must ere long bear its legitimate fruits in awakening public attention in hastening the enforcement of the necessary remedies.

In the meantime let us be patient and labor on. Not to make an invidious comparison with the work in other associations, we cannot refrain from a special allusion to the discussion of the school question before the Social Science Association, at its recent meeting in Saratoga. In this we have a typical illustration of the direction in which medical influence can be exerted with the greatest benefit to all concerned. To the profession is due almost all the credit which may come

from the agitation of the questions bearing upon school hygiene; and that influence is being created in high places is another evidence of the power of professional opinion and the force of professional character. In the reports of this Association, published by the daily press, side by side with elaborate papers on civil service reform, the money and labor question, we have full abstracts of papers on near-sightedness and deafness in school children, on contagious diseases in schools, on school architecture, drainage, etc. Here, too, is an illustration of the necessity of leaving the discussion of one of the most important reforms of the age almost entirely in the hands of the medical profession. The manner in which they have treated the subject from the beginning shows that they are in earnest in their laudable efforts. The principles upon which these reforms must be founded are well enough understood by the profession at large; it only needs to convince the public of their necessity to have the remedies applied. It will not serve our present purpose, then, to refer in detail to the measures proposed; but we cannot refrain from expressing our hearty commendation of the manner in which the different subjects were presented by those gentlemen who took part in the discussion. Notably among these were Drs. O'Sullivan and Loring, of New York; D. F. Lincoln, Edes, Bowditch, Blake, and Nichols, of Boston; Spalding, of Maine, and Hewitt, of Providence.

Reports of Societies.

AMERICAN GYNECOLOGICAL SOCIETY.

FIRST ANNUAL MEETING.

WEDNESDAY, SEPTEMBER 13.—FIRST DAY.—MORNING SESSION.

THE American Gynecological Society convened in the city of New York Sept. 13, 1876, and was called to order at 10 A.M. by the President, DR. FORDYCE BARKER.

DR. T. G. THOMAS, Chairman of the Committee of Arrangements, gave the guests, and the members, who had honored the Society with their presence, a most cordial welcome, and moved that Dr. Robert Barnes be invited to take a seat upon the platform.

The following gentlemen were received as members by invitation: Drs. Trenholme, of Montreal; Hadden, of Toronto; Tagliaporo, of Georgia; Rosebrugh, of Hamilton, Canada; and Reamy, of Cincinnati.

The first paper for the session was read by DR. T. ADDIS EMMET, of New York,

ON INCISION OF THE CERVIX UTERI.

In this paper was given an analysis of 345 cases of different forms of flexures treated in Dr. Emmet's private hospital, and the tabulated statistics made from observations upon 2,447 cases suffering from various diseases and injuries peculiar to women.

Dr. Emmet recognized two classes of cases: First, where the flexure was congenital and situated at or below the vaginal junction. Dysmenorrhœa, if present, was present at the beginning of the flow, but was relieved as soon as the flow was established, because of the straightening of the cervix in consequence of the menstrual congestion, and for the relief of this flexure he divided the posterior lip backward, in the median line, with a pair of scissors. The operation was attended with but little danger if the patient was properly cared for, from the fact that the organ was otherwise in a comparatively healthy condition. Second, where the flexure was in the body of the uterus, either anteversion or retroversion, and was developed subsequent to puberty. Dysmenorrhœa was present all through the flow, for the obstruction became exaggerated by the menstrual congestion. That was due to the fact that the disease was confined chiefly to one side of the organ, and the circulation was comparatively free on the opposite side. In the second class of cases, if the flexure had long existed, the tissues, at the point of greatest constriction, gradually underwent fatty degeneration from pressure, and absorption occurred, causing a permanent deformity, as after caries of the spine. When a case of that variety was met, after careful treatment had been instituted and a point reached at which all tenderness on pressure had been removed, and not until then, it was often judicious to divide the cervix backward, and to incise forward the seat of flexure above, sufficiently to open the canal. To operate early in the second class of cases, before the patient was cured, that is, before the congestion and inflammation were removed, was regarded as malpractice.

THE PRESIDENT remarked that the paper before the Society embraced new pathological views which should be carefully scrutinized, and to that end he hoped the discussion would be frank, bold, and decided, and free from all personalities. It had been expected that Dr. Sims, of New York, would be present, as he had indicated his intention of so doing in a letter sent to the President; but, it was to be regretted, he was absent.

DR. E. R. PEASLEE, of New York, then opened the discussion by saying that he accepted every word Dr. Emmet had said, as far as it was practical; the statistics, as a matter of course, should be accepted. He was glad to have the opportunity to make that statement, for he had been misunderstood by many with regard to his ideas upon this subject that had been expressed in a paper read before the New York Academy of Medicine early in the summer.

Dr. Peaslee then read from his paper, of which an abstract was published in THE RECORD for July 24, 1876, what he had stated with reference to posterior discision of the cervix uteri, bilateral discission, and the superficial incision, and disputed the assertion that he had made claims to priority for the latter. He had brought the superficial incision prominently before the profession, but had not intended to make any imperious claim upon it. The doctor further remarked that he had been told Dr. Sims would be present, and would annihilate the paper which he had read, and he had invited some of his friends to be present as mourners upon the occasion, but he was sorry to learn that Dr. S. was not to be present. He wished the fullest criticism of his paper, for he was entirely above all personal considerations in the matter.

THE PRESIDENT then introduced DR. ROBERT BARNES, of London, who, after thanking the Society for the cordial greeting which it had given him, remarked with regard to many cases of retroversion becoming cases of retroflexion about the time of puberty, as mentioned in Dr. Emmet's paper, that it was a difficult matter to determine, as we did not have the

opportunity to examine the patient so that we might know what the precise condition was. He was satisfied, however, that many of the cases were congenital, but at what time they began to develop the form of displacement present when examined, he was unable to say, and could hardly understand how they should begin as cases of retroversion. Dr. Barnes was of the opinion that we could practically disregard the idea of stenosis of the os internum, for he had never met with a case in which the sound could not be passed through that opening. It might be narrowed by flexure, but then it was not cured by incision, and such operation under those circumstances was unnecessary. He regarded incision as a dangerous operation. In a great majority of cases dysmenorrhœa could be relieved by enlarging the os externum simply, and if flexure was present to some extent it became relieved by the same operation. The incision in such cases need not be large, and could be most conveniently made by means of scissors. In some cases it might be necessary to repeat the operation. The patient required preparation, and should remain in bed for a week after it had been performed. Even with the modified form of operation he had three fatal cases.

Dr. J. P. White, of Buffalo, remarked that if called upon to adopt either Simpson's, Sims's, or Peaslee's operation, he should adopt the latter and make the superficial incision. He was of the opinion that Dr. Emmet in his paper had given too little attention to stenosis of the cervical canal, and he believed that it might be present independent of flexure. The doctor then proceeded to make some remarks upon the treatment of narrowing of the canal of the cervix, no matter what the cause might be upon which it depended. Operative procedure was, in his opinion, the only means which would afford relief. He made the bilateral incision by preference, and perhaps a little deeper than recommended by Dr. Peaslee. He performed the operation with a small knife, perhaps no larger than a tenotomy knife, with long handle, and kept the edges of the wound separated by cotton, and subsequently by means of a dilator which he exhibited. Almost all cases of dysmenorrhœa had been immediately benefited by this procedure. He made the incision *early* in the treatment of dysmenorrhœa, and expected the cure to go on *pari passu* with the cure of the wound in those cases where there was present great systemic disturbance.

The discussion was continued by Drs. Howard and Wilson, of Baltimore; Drs. I. E. Taylor and Peaslee, of New York; Dr Smith, of Philadelphia; Dr. Byrne, of Brooklyn; Dr. Rosebrugh, of Canada, and Dr. Chadwick, of Boston.

After the appointment of the Nominating and Auditing Committees, the Society adjourned to meet at 3 P.M.

First Day.—Afternoon Session.

The Society was called to order by the President, and the following gentlemen named as invited guests: Drs. Wm. Fox, of Madison, Wis.; G. E. Sussdorff, of Macon, Georgia; Charles Shepard, of Grand Rapids, Mich.; F. N. Evelith, of Waldoboro, Me; T. P. Seeley, of Chicago, and Dr. John T. Hodgen, of St. Louis.

The first paper for the afternoon session was read by Dr. A. J. C. Skene, of Brooklyn,

On Cicatrices of the Cervix Uteri and Vagina.

In this paper Dr. Skene considered in a brief and concise manner the causes, symptoms, and physical signs to which such cicatrices might give rise, and then studied the treatment under two heads: first, guarding against their formation; second, the treatment direct for the relief of the condition present.

Under the first head it was maintained that lacerations should be immediately brought together by sutures. When it became necessary to apply caustics, a portion of the mucous membrane should be left untouched, if possible, so that the eschar would not completely circumscribe the canal.

The indications under the latter head were to relieve pain, prevent contraction, and when deformities existed to correct them. Those requirements could be best fulfilled by complete removal of the cicatrix; but that was not always practicable, however, and should never be undertaken in cases where the scar was attached to the subjacent tissues. Shortening of the cicatrix could be prevented by cutting it in one or more places, and then using a tampon or pessary to keep the edges of the woand separated. When it surrounded the os externum, it should be divided upon two sides, and a sea-tangle tent worn during the process of healing.

The frequent use of the sound might answer the same purpose. The elm-bark tampon was highly recommended, and it was thought that the normal parts of the vagina could be enlarged, so as to compensate, to some extent at least, for the loss of room occasioned by the contraction of the cicatrix. For the relief of the pain and tenderness, the incision sometimes gave immense relief. Tr. opii, aconite, and iodine combined was recommended to soften the cicatrix. The doctor then related cases illustrative of the statements made in his paper.

Dr. Trenholme, of Montreal, commended the principle of continued pressure with slight incisions in the treatment of this class of cases, and furthermore expressed the hope that the Association would express itself somewhat strongly concerning the indiscriminate use of caustics in the treatment of diseases of women.

Dr. Byford, of Chicago, spoke very favorably of the slippery elm tampon after division of the cicatrix.

Dr. Emmet drew attention to one point which had been omitted by the author of the paper, namely, the effect upon the nervous system produced by the cicatrix. He was of the opinion that the man who succeeded best in the treatment of uterine disease was the one whose treatment was followed by the smallest amount of cicatricial tissue. For the nerves become involved in the scar, and give rise to immense trouble in the way of neuralgic pain, especially where the parts about the neck of the uterus and the urethra were affected.

Dr. E. W. Jenks, of Detroit, then read a paper

On the Uses of Viburnum Prunifolium in the Treatment of Diseases of Women.

The bark of the root should be used. A fluid extract was exhibited prepared from that portion of the plant, and was recommended in drachm doses as a uterine sedative of great service, especially in the management of cases of threatened abortion. It was regarded as serviceable in the treatment of all uterine diseases characterized by loss of blood, such as menorrhagia, metrorrhagia, etc.; and also in the treatment of nearly all forms of dysmenorrhœa. It was considered as being insufficiently sedative to relieve spasmodic and neuralgic dysmenorrhœa.

Dr. Bates, of New York, remarked that he had used the drug to a certain extent, and that it certainly had power to prevent abortion, especially in those

instances where the accident had become habitual. He thought its action was tonic and sedative.

Dr. White, of Buffalo, was unable to see how any uterine sedative could arrest the changes which took place in the ovum, and upon which the great majority of abortions depended. Still he suggested that it be thoroughly tested by the profession, for at present we had no uterine sedative among our commonly employed therapeutical agents.

Dr. Jenks, in response to several inquiries, remarked that he had used the drug somewhat empirically, had no theory concerning its physiological action, and that he would not hesitate to substitute it for opium.

Dr. Joseph A. Eve was named as an invited guest, and invited to a seat upon the platform.

Dr. T. Parvin, of Indianapolis, reported a case of

ABNORMAL MENSTRUATION,

in which there was an oozing of blood every twenty-eight days from the lower lip and gums, and continued for five or six days. The hemorrhage was mostly from the gums.

The last paper for the afternoon session was one from Dr. Storer, of Boston.

ON THE IMPORTANCE OF THE UTERINE EBB AS A FACTOR IN UTERINE SURGERY.

Dr. Storer believed that there was an ebb and flow in the female body especially, which occurred regularly like the tides, or day and night, and which should be observed carefully if the operator would have the greatest possible success attend his operations. He had performed serious surgical operations upon the pelvic organs during the catamenial flow, and with success. But, all things being equal, pelvic operations should be performed about one week after the menstrual period had ceased, or at a period corresponding to that time in cases where the catamenial discharge was not present.

Dr. Campbell, of Georgia, remarked that he fully endorsed the principle set forth in Dr. Storer's paper, and that he had acted in accordance with it from the beginning of his gynecological operations. Whether the operation was upon the uterus, vagina, or even for the removal of hæmorrhoids, he had been accustomed to perform it about a week subsequent to the cessation of the catamenial discharge.

The Society then adjourned to meet at 10 A.M., September 14.

THURSDAY, SEPTEMBER 14.—SECOND DAY.—MORNING SESSION.

The hour of 10 A.M. having arrived, the Society was called to order by the President, and the reception of two communications announced, which were read by the Secretary.

On motion, it was decided to comply with the request embodied in each, as far as possible, and with respect to Dr. Dalton's communication, it was moved to extend to him the invitation that he should make his report to this Association at its next annual meeting. The communication related to the corpus luteum.

The following gentlemen were elected members by invitation: Drs. Ira Russell, of Massachusetts; Ward, of Alabama, and B. B. Brown, of Baltimore.

Dr. Byford, Vice-President, was called to the chair.

The President's address being next in order, Dr. Barker delivered an interesting and valuable address, which was listened to throughout with the closest attention. The character and ability of the papers, which were to give the proper status to the Society, were carefully referred to, and a high-toned position taken relative to the discussions to which they might give rise. The doctor argued in favor of demanding papers of the highest order from candidates for admission, and believed that, when conducted with care and in the proper spirit, the most valuable discussions were oral.

A comparison between the period at which this Society started and that which the year commemorated was then instituted, and in it was clearly brought out the progress which the science and art of medicine has made within one hundred years, as especially pertaining to the department of obstetrics and gynecology. "Yet," said the speaker, "no definite future has been obtained; no man can rely upon his present achievements."

In conclusion, the hope was expressed that the Society might prove itself one which should command the respect and approval of the highest and most cultivated judgment of the scientific world, and not incur the reproach which Job in his bitterness uttered, "Ye are all physicians of no value."

On motion of Dr. Chadwick, of Boston, a vote of thanks was tendered the President for his most excellent address.

Dr. Robert Barnes, of London, was next introduced, and read a paper

ON SOME OF THE RELATIONS OF PREGNANCY TO GENERAL PATHOLOGY.

The name of the reader was sufficient to secure for him the closest attention, while bringing out interesting points by a comprehensive consideration of the general influence of pregnancy upon the female organism.

The influence of menstruation, ovulation, and many other conditions upon the general economy had been carefully studied, but they had been considered in too detached portions. For example, if the study of albuminuria or Bright's disease was limited to those cases occurring in men, or in women outside of pregnancy, we should be of the opinion that organic change in the structure of the kidney was an essential condition to the development of the disease. The condition of pregnancy threw an entirely new flood of light upon that interesting but serious affection.

From that point Dr. Barnes proceeded to study the chemical change in the constitution of the blood which occurred during pregnancy, together with the change in the dynamics of the circulation. The changes in the glandular system were referred to, notably those taking place in the thyroid, spleen, liver, kidney, etc.

Light might be thrown upon diseases of the eye by studying them in connection with pregnancy, and a form of amaurosis associated with that condition was mentioned, and from which recovery took place.

The changes in the function of respiration in pregnancy were referred to, and the influence which carbonic acid gas had in producing abortion was considered at some length. There was no evidence that the disturbances in the skin could produce the same result, but it was maintained that defective action of this great glandular surface might increase the defective action of the liver, kidneys, and lungs.

The influence of pregnancy in favoring coagulation of the blood was considered, and the three factors found which predisposed to the formation of thrombi; namely, some degree of arrest in its movement, the peculiar condition of the blood, and the introduction of some foreign material that favored the precipitation of fibrin.

Hemorrhages occurring in pregnancy might evidence a high arterial tension, and in many cases be a salutary measure. Could we, by means of the sphygmograph, or any other instrument, tell when arterial tension was rising too high, should we not undertake the removal of the pressure by drawing a small amount of blood; or at least increase the watery secretion from the bowels by means of hydragogue cathartics?

The paper was replete with suggestions, but our space does not permit a more extended abstract.

On motion made by DR. PEASLEE, a vote of thanks was extended to Dr. Barnes for his able paper.

THE PRESIDENT remarked that the paper was so suggestive in all directions in connection with general practical pathology, it certainly must be difficult to discuss it; yet he would call upon Dr. Peaslee, who was so distinguished a physiologist before he came to be so eminent a gynecologist, to open the discussion.

DR. PEASLEE remarked, with regard to the main proposition of the paper, that very much could be learned in general pathology from a careful study of special pathological conditions which accompanied and were brought about by utero-gestation. For, in that condition, everything was subordinated to the development of the uterus on the one hand, and its contents on the other. Every function of the body was modified, and most of the suggestions made by Dr. Barnes we were compelled to acknowledge as true and conscientious statements. Like the saying of the poet, "They have all been felt before, but never so well expressed."

Dr. Peaslee referred to the value of the paper in another respect; namely, as bearing upon certain conditions following parturition, or, it might be, independent of that act. When sub-involution or chronic passive congestion was present, he regarded the condition as one in which there was at work, as it were, a continued pregnancy; and more or less derangement of the liver, lungs, the kidneys and stomach existed as long as either those conditions remained. As far as effects were concerned they were cases of continued pregnancy, and it was important that such factor should be recognized.

DR. W. T. LUSK, of New York, remarked that he had been especially impressed with the remarks Dr. Barnes had made concerning the influence of pregnancy upon malarial poison in the system, and related a case in which the woman had been the subject of malarial poisoning, but in whom chill after chill was developed immediately upon her subsequent pregnancy, and continued in spite of all treatment throughout utero gestation. Immediately after confinement the attacks ceased.

Dr. Lusk inquired of Dr. B. whether any experiments had been made which proved that carbonic acid gas had power of acting in an isolated manner upon any organ or organs in the body. The paper was further discussed by Drs. Richardson, of Boston, and Noeggerath, of New York.

DR. BARNES, in closing the discussion, remarked that the conditions to which Dr. Peaslee had drawn attention were very striking illustrations, and extremely valuable, because they showed that the practical gynecologist could not in any pure sense be a specialist. He must extend his observations to the general system as well as direct attention to the organ at fault. True specialists were those who attended to diseases of the nervous system, liver, etc., and neglected the uterus. The true gynecologists were the "all around" practitioners. The case cited by Dr. Lusk illustrated the statement already made that it was hardly worth while to treat many conditions occurring in pregnancy as long as the pregnancy continued; and when that condition had passed most of the derangements would have disappeared. Dr. Barnes, in answer to the question asked by Dr. Lusk, referred to a number of instances where abortion had followed the inhalation of poisonous quantities of carbonic acid gas, facts which seemed to show that it had a distinct effect upon the gravid uterus. It was also a well-established fact that carbonic acid gas stimulated the action of inorganic muscular fibre.

The next paper was read by DR. BYFORD, of Chicago,

ON THE SPONTANEOUS AND ARTIFICIAL DISINTEGRATION OF FIBROUS TUMORS OF THE UTERUS.

The history of three cases was related. The disintegration in two of them was believed to be due to the influence of ergot.

In a majority of cases the drug could be tolerated by the stomach and might be administered in twenty or thirty drop doses twice or three or four times a day, and continued for a year, without producing any toxic effects. Sometimes a few doses only were necessary to effect all that was desired.

Dr. S. S. Purple, President of the New York Academy of Medicine, was made a member by invitation.

The Society then adjourned until 3 P.M.

SECOND DAY.—AFTERNOON SESSION.

The Society was called to order by the President, and the first paper read by DR. T. G. THOMAS, of New York,

ON ABDOMINAL PREGNANCY TREATED BY GASTROTOMY.

The paper contained the report of a case with comments, and the following points were noted. Early diagnosis was made important, and prompt surgical interference recommended, not uniformly, but in certain cases non-interference would be criminal. No positive rule could be laid down. In the present instance fluid from the sac was submitted to an excellent microscopist, who declared that it contained what he believed to be the ovarian corpuscle. The placenta was left *in situ*; the external wound was kept open by a drainage tube; the sac was washed out with antiseptic injections, as symptoms of septicæmia were developed on the fourteenth day; and in the fifth week the placenta, partially decomposed, appeared at the opening and was removed. The child was well developed, but its death had been caused by a hair tightly encircling the funis and cutting off all circulation.

When the peritoneum was reached it was found so hypertrophied that had not the doctor been positive in his diagnosis he should have regarded it as a condition associated with ovarian cyst and proceeded to peel it off from the abdominal walls, and probably brought about a fatal result.

DR. BYFORD, Vice-President, in the Chair, called upon Dr. Barnes to open the discussion. The doctor made some interesting remarks touching the difficulty of diagnosis, and believed that the diagnosis by the presence or absence of what had been called the ovarian corpuscle was unsafe. He coincided with Dr. Thomas in the view that the placenta should remain undisturbed, but he was not quite so certain that the external wound should be kept open. The propriety of opening the wound upon the first development of symptoms of septicæmia was perfectly clear.

DR. ENGELMANN, of St. Louis, thought that a differ-

ential diagnosis between ovarian cyst and other conditions could not be made by microscopical examination.

Dr. Drysdale, of Philadelphia, remarked that he had made over 1,500 examinations of fluid from the abdomen, and had not failed in a single instance, when proper care was exercised, in making a differential diagnosis between ovarian and any other form of abdominal tumor. The doctor stated briefly the tests which he commonly employed to determine the character of the cell.

Dr. Chadwick's experience had been unfavorable to the so called ovarian corpuscle as a pathognomonic cell.

Dr. Byford's experience, as far as it went, in thirty or forty instances, corroborated that given by Dr. Drysdale.

Dr. Thomas, in closing the discussion, remarked that the best microscopists of this city had failed to make a diagnosis of ovarian tumor by a microscopical examination of the fluid, and he had come to regard it as an unreliable aid. Still he did Dr. Drysdale credit by saying that the diagnosis had been correct, as proved by operation, in every instance in which he had submitted fluid to him for such examination. With regard to the propriety of leaving an opening for the escape of the placenta the question was not whether it might not be removed by nature after the opening was closed, but whether it would not be safer for the patient to leave the opening for the discharge of detritus. He regarded it as an unsafe conclusion that when septiæmia showed itself we might then make an opening.

PNEUMATIC SELF-REPLACEMENT IN DISLOCATION OF THE GRAVID AND NON-GRAVID UTERUS

was the title of a paper read by Dr. H. F. Campbell, of Georgia.

The paper was discussed at some length by Drs. Parvin, Emmet, Mundé, Smith, of Philadelphia, Chadwick, Peaslee, and Wilson.

The Society then adjourned, to meet at 10 A.M. on Friday, September 15.

Friday, September 15.—Third Day.—Morning Session.

The Society was called to order by the President, and Dr. Edward Wilson, of Philadelphia, elected member by invitation.

Dr. Byford's paper upon the spontaneous and artificial disintegration of uterine fibroids being open for discussion,—

Dr. Atlee, of Philadelphia, remarked that he should restrict what he had to say to the natural efforts of the womb to disintegrate these tumors, and thought that such disintegration was confined to the submucous variety. In such cases there was no doubt but that when the capsule became inflamed, ulcerated, and ruptured, the natural efforts of the uterus might force the tumor from its cavity into the external world. The vitality of the tumor was not great, and when exposed to the atmosphere by rupture of the capsule, it took on a species of decay, analogous to that seen in fruit, or the dry-rot in wood, which extends from one point to another, until the greater portion of the tumor might be subjected to that destructive change. When such condition was present, the tumor should be rapidly expelled or quickly removed by artificial means, for there was great danger of systemic poisoning. In the meantime, such toxic state should be guarded against by the free use of antiseptic injections. Dr. Atlee spoke of fibroids in connection with parturition, and in conclusion sustained the position taken by Dr. Byford in his paper.

Dr. Goodell, of Philadelphia, mentioned a case in which the fibroid was situated in the fundus of the uterus, the capsule was incised, ergot administered, and a large portion of the tumor thrown off in fragments.

Dr. Drysdale, of Philadelphia, called attention to the use of large doses of ergot in this connection, and stated that he had administered ℥ ss. doses of Squibb's fl. ext., t. i. d., continuously for a year without producing deleterious effects.

Dr. Emmet, of New York, was of the opinion that only when the tumor was situated so as to bring the gravity to bear in effecting its expulsion was ergot of any service as an expulsive agent.

Dr. Thomas, of New York, believed that the action of ergot in these cases was two-fold, and that the two should not be confounded. First, it unquestionably assisted the uterus in expelling the tumor, when situated so that it could be forced into the uterine cavity. Second, Hildebrandt had shown conclusively, that ergot affected the blood-vessels of an interstitial tumor, in accordance with the same law which governed its influence upon blood-vessels in other parts of the body. That action should not be overlooked, and it was by no means secondary in importance.

Dr. E. Noeggerath, of New York, then read a paper on

LATENT GONORRHŒA, ESPECIALLY WITH REGARD TO ITS INFLUENCE ON FERTILITY IN WOMEN,

in which he set forth the doctrine that gonorrhœa persisted for life in certain sections of the organs of generation, notwithstanding its apparent cure; and maintained that that fact explained to some extent the prevalence of uterine disease in large cities; why blooming girls faded so soon after marriage; why treatment of certain cases of uterine disease seemed to have no effect; why sterility was so abundant.

The paper was somewhat sharply criticised by Drs. Trenholme, of Montreal; Engelmann, of St. Louis; Chadwick, of Boston; and Johnson, of Washington.

Dr. Noeggerath replied with considerable vigor.

The Secretary then read a paper which had been received from Dr. Albert Wiltshire, of London, England, on

DEATH FROM URINÆMIA IN CERTAIN CASES OF MALIGNANT DISEASES OF THE UTERUS.

The paper was discussed by Drs. Parvin, of Indianapolis; Campbell, of Georgia; Skene, of Brooklyn; Wilson, of Baltimore, and the President.

Dr. G. J. Engelmann, of St. Louis, then presented the abstract of a paper on

MENSTRUAL HYSTERO-NEUROSIS OF THE STOMACH.

On motion, it was resolved that the Society did not hold itself responsible for any views expressed in papers that might appear in its Transactions, but that they were to be regarded simply as the views of the authors.

The Society adjourned to meet at 3 P.M.

Third Day.—Afternoon Session.

The Society was called to order by the President.

The first order of business was the reading of a paper and presentation of specimens by Dr. E. R. Peaslee, of New York, entitled

SOLID UTERUS—BOTH OVARIES REMOVED FOR THE RELIEF OF EPILEPTIC SEIZURES BELIEVED TO DEPEND UPON OVARIAN IRRITATION.

Dr. Peaslee's operation was performed through the abdominal wall. Fatal peritonitis ensued.

Dr. Trenholme, of Montreal, related two cases in which he had removed the ovaries, and recovery followed in both instances. One operation was supra-pubic and the other vaginal. The paper was further discussed by Drs. Thomas, Noeggerath, and Emmet.

Dr. Gaenslen, of Texas, was elected member by invitation.

Dr. W. Goodell, of Philadelphia, then read a paper, entitled

CLINICAL MEMOIR ON SOME OF THE GENITAL LESIONS OF CHILD BED,

in which he maintained that the condition of the woman was bettered, when laceration of the perineum occurred, by closing it at once with silver-wire sutures. He was by no means so sure what should be the course of the physician in cases of laceration of the recto vaginal septum proper. Such rupture usually escaped notice because it healed spontaneously.

Dr. Emmet favored closure with sutures as soon as possible.

Dr. Campbell favored immediate closure, especially in partial lacerations.

Dr. Wilson favored immediate closure in a majority of cases.

Dr. Skene urged immediate closure of the laceration by sutures.

Dr. Jenks remarked that he should not expect union to occur if the laceration was united at once after considerable manipulation about the parts had been necessary to effect the delivery.

Dr. Howard remarked that he had been more successful in the performance of the primary than the secondary operation.

The President was compelled to differ from the majority of opinions expressed upon the question.

The President also announced that he had received a letter from Dr. Sims, in which he stated that it was one of the great disappointments of his life that he had not been able to be present. He had not yet sailed from Europe.

The papers announced upon the programme were regarded as having been read by title, and referred to the Publication Committee. They were as follows:

Battey's Operation for the Extirpation of the Ovaries, by Dr. R. Battey, of Rome, Ga.

Hydrate of Chloral in Obstetric Practice, by Dr. W. L. Richardson, of Boston.

A Case of Labor Complicated with Four Large Uterine Fibroids and Placenta Previa; also a paper on Masturbation in Women, a report of seventeen cases treated with bromide of potash, by Dr. J. R. Chadwick, of Boston.

A paper from Lawson Tait, of England.

Case of Cystic Tumors of the Pelvis, by Dr. G. H. Bixby, of Boston.

What is the History of Calculi formed in the Bladder after Operation for Vesico-vaginal Fistulæ? by Dr. H. F. Campbell, of Augusta, Ga.

The officers of the Association for 1876 were re-elected.

The hour for adjournment having arrived, the President congratulated the Fellows upon a most auspicious inauguration of the Society, and declared it adjourned to meet at Boston in the last week of May, 1877.

Scarlet Fever propagated from Milk. Dr Buchanan, in his report on a recent outbreak of scarlet fever in South Kensington, says that the disease was apparently propagated through the agency of milk.

Correspondence.

SIMS' AND NOTT'S SPECULUM.

To the Editor of The Medical Record.

Dear Sir:—In your journal of Sept. 9th there is a cut of a combined Sims' and Nott's speculum, with a description of the instrument by Walter R Gillette, M. D., of New York, from which paper I quote as follows: "I present herewith a cut of a combined Sims' and Nott's speculum which was made at my suggestion two years ago by Dr. Leonard, of Shepard & Dudley's."

I regret that the Doctor had not used the instrument before, and am gratified that he now employs it in preference to many others. I have liked it for over *four* years, and have had one that length of time in daily use which answers in every respect to the cut and description of Dr. Gillette, even to Van Buren's curve in the Sims' blade for rectal examination. To my knowledge, there are quite a number of the same pattern of instruments, and of the same age as mine, in existence. Four years ago last February I suggested to Mr Stohlmann, of Tiemann & Co., New York, certain improvements in Nott's speculum. Mr. S. further improved the plan which I presented to him, and manufactured the instrument so well delineated and described in the Record of September 9th.

E. W. Jenks.

IS ALCOHOL A FOOD?

To the Editor of The Medical Record.

Dear Sir:—In your report of the late meeting of "The International Medical Congress," an abstract of a paper appears on "Alcohol in its Therapeutical Relations as a Food and a Medicine," by Dr. E. M. Hunt, of New Jersey, together with the following conclusions of the author, which "were ordered to be transmitted to" certain temperance organizations:

"1. Alcohol is not shown to be a definite food by any of the usual methods of chemical analysis or physiological investigation." [In order to be brief, we will not quote the remaining three conclusions, as they have no direct reference to the comments which we intend to make on the first.]

A paper like this, in which the author professes to have examined the most important researches on alcohol that were ever made, and which receives the sanction and ratification of "The World's Medical Congress," comes before us with more than ordinary gravity and authority, and hence it demands our serious consideration.

In regard to the first proposition we can only say that, aside of the false and erroneous light in which it undertakes to place alcohol, it is constructed in the most vague and unfortunate language. It is a conclusion without containing any moral, for it leaves it an open question, after all, whether alcohol is actually a food or not. For if "alcohol is not shown to be a —— food by any of the usual methods of chemical analysis or physiological investigation," it can perhaps be, or is demonstrated to be, a food by some unusual method of investigation. We have not read more of Dr. Hunt's paper than the mere abstract which is given in your journal, but if the conclusion which the author draws is in accordance and has any connection with the premises of his paper, then in every sense of jus-

tice and honor do we enter our most earnest protest against what seems to us a most ungenerous attempt at misrepresenting the views entertained on this question by the late Dr. Anstie, whose experiments and conclusions have received the attention of the Doctor, and at whose hands they are made to appear as if they were wholly demolished, and that in a single essay, too! Now, in the name of scientific medicine, we deny *in toto* that the researches of Dr. Anstie, let alone those of Dr. Binz, reference to which is also made, would lead us to believe that alcohol is not a food; and on the contrary, we most emphatically assert that alcohol is conclusively "shown to be a —— food" by his own chemical analysis and physiological investigations, which becomes very evident to every one after a candid, thorough, and intelligent perusal of his work in this direction. And the investigations of Dr. Dupré, as well as those of Drs. Thudicum, Schulinus, and Baudot, establish the same results. We do not wish to appear uncharitable in this matter, but when a body of medical men causes such a sweeping *pronunciamento*, as this was designed to be, to be heralded forth to the unprofessional public, on as important a subject as that of alcohol, then in all fairness let that body first consider whether its action is in conformity with the latest development which science can command on that question.

THOMAS J. MAYS, M.D.

UPPER LEHIGH, PA., Sept. 25, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Sept. 24th to Sept. 30th, 1876.

VOLLUM, E. P., Surgeon. Granted leave of absence for twenty days. S. O. 199, A. G. O., Sept. 25, 1876.

BYRNE, C. C., Surgeon. Granted leave of absence for one month. S. O. 120, Dept. of Dakota, Sept. 25, 1876.

FRANTZ, J. H., Surgeon. Granted leave of absence for two months, on surgeon's certificate of disability. S. O. 195, Div. of the Atlantic, Sept. 28, 1876.

GREENLEAF, C. R., Surgeon. Leave of absence extended one month. S. O. 194, Mil. Div. of the Atlantic, Sept. 27, 1876.

WATERS, W. E., Asst. Surgeon. Granted leave of absence for four months. S. O. 201, A. G. O., Sept. 27, 1876.

DE GRAW, C. S., Asst. Surgeon. Relieved from duty at Fort Davis, Texas, to comply with orders from A. G. O. S. O. 172, Dept. of Texas, Sept. 16, 1876.

KINSMAN, J. H., Asst. Surgeon. Assigned to duty at Fort Sully, D. T. S. O. 121, Dept. of Dakota, Sept. 27, 1876.

BEDAL, S. S., Asst. Surgeon. Assigned to duty at Fort Duncan, Texas. S. O. 174, Sept. 20, 1876.

TURRILL, H. S., Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Davis, Texas. S. O. 172, C. S., Dept. of Texas.

COMEGYS, E. T., Asst. Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month; and on expiration of leave assigned to duty at San Felipe, Texas.

JACKSON, DONALD, Asst. Surgeon. Died at Woodville, Ontario, Canada, on Sept. 22, 1876.

CUNINGHAM, T. A., Asst. Surgeon. Assigned to duty at Fort Stevenson, D. T. S. O. 121, C. S., Dept. of Dakota.

THE EX-EMPRESS Charlotte is reported to have confirmed dementia.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending September 30, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

Sept. 30	1	22	12	2	13	34	6

THE ENGLISH VIVISECTION BILL.—The sentiment of the profession in regard to the justice of the proposed Act is likely to be in a measure respected. Mr. Roebuck, an English statesman, in a recent reply to a toast at a dinner of the British Medical Association, struck the key-note of conservatism when he said that Parliament might have conceded to the profession the power of deciding whether experiments and the pain connected with them, were or were not necessary.

ADVERTISING FOR PRACTICE.—Some London surgeons have established Provident Dispensaries, the plan of operating which is to furnish advice and medicines in consideration of small weekly fees in advance. In order to make these enterprises pay, the proprietors boldly advertise for patients, much to the disgust of respectable practitioners.

PHOTO-MICROGRAPHS.—The well-known London house of Macmillan & Co., publishers of "The Practitioner," have undertaken the publication, in England, of "Micro-photographs in Histology," the monthly work conducted by Drs. Seiler, Hunt, and Richardson.

QUACKERY IN FRANCE.—The laws of France provide that no remedy whatever can be sold, or even used, without first being examined by a special Committee of the Faculty of Medicine, and yet quacks make fortunes in that country.

HORSE-FLESH AS AN ARTICLE OF DIET is advised by Mr. Decroix, of Lyons, when such flesh is required to be eaten raw. By such means tapeworm, so common when the flesh of the ox and sheep is taken in this manner, is prevented.

THE regular term of the Bellevue Hospital Medical College was opened on Wednesday evening, Sept. 27, 1876, by an address delivered by Prof. A. B. Crosby.

THE AUSTRIAN MEDICAL CONGRESS.—The second general congress of the Austrian profession terminated at Vienna on the 2d of August.

COMPULSORY VACCINATION.—The Scandinavian physicians, at a recent congress, strenuously advocated compulsory vaccination.

WRESTLING.—The *Dublin Med. Press and Circular* has a strong article in favor of wrestling from a gymnastic point of view.

INTERNATIONAL EXHIBITION IN AFRICA.—Africa is to have an International Exhibition, to open in February next.

MANUFACTURED BUTTER.—There is a large establishment at Marseilles for the manufacture of artificial butter.

ORTHOPÆDIC HOSPITAL OF IRELAND.—A National Orthopædic Hospital has been opened in Dublin.

Original Communications.

SALICYLATE OF SODA IN RHEUMATISM.

By A. CLARK, M.D.,

PROF. OF PATHOLOGY AND PRACTICAL MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

My acquaintance with practice in the New York hospitals began in 1834. Since that time, either at home or abroad, officially or as a volunteer, I have been a very frequent visitor at one or more of these, or similar institutions. In this period of forty-four years the treatment of acute rheumatism has undergone many changes.

At first colchicum and actea racemosa, in tincture, separately or united, were generally relied on; calomel was at the same time often prescribed. After these followed quinine in full doses; then the nitrate of potash, an ounce or more daily, dissolved in a quart or more of water. The free use of lemon-juice was next tried. So far there was reason to doubt whether any of these medicines, except colchicum, aided much in the cure; in other words, whether the disease, after running a certain course, did not terminate spontaneously. The curative effects of colchicum, in full doses, during all these changes were often demonstrated, but serious accidents were occurring in its use, and the profession was searching for a safer treatment.

At length Dr. Fuller, of London, proposed and advocated the alkaline method. The carbonates, or convertible salts of soda and potash, were given in such quantity as to make the urine alkaline in two or three days. Then it really seemed as if we had found a safe and speedy remedy. There were cases that resisted it, but the greater number yielded. The pain subsided on the second, third, or fourth day, the stiffness remaining a day or two longer. This result, so far as it could be obtained, was a great gain. It has been observed that the acute inflammations of the pericardium and endocardium which attend acute articular rheumatism, are disposed to wait till the fifth day of the primary disease, or even a longer time. To cure the primary disease before the fifth day is, in a great majority of cases, to prevent the cardiac complications. It is true that in rare instances the cardiac inflammations have been the first manifestation of the rheumatic diathesis, the affection of the joints following one or more days after. It is equally true that the cardiac inflammations have followed that of the joints earlier than the fifth day. Still, the rule has an application sufficiently extended to illustrate one of the important advantages of the Fuller treatment.

Lately the claims of salicylic acid to the first place among the anti-rheumatics have been strongly urged. The following report of its use at Bellevue Hospital may help the profession to form a judgment regarding its virtues. It embraces all the cases received in my wards, from the 1st of April to the 1st of June, that could be called *acute* rheumatism—eleven in all. Short abstracts from the record of these cases have been made at my request by Dr. Kendall and his assistants, from the Hospital Case-Books. Each is full enough to show the general effects of the medicine; but as the effect of it on the temperature and pulse is not always mentioned, I can add that its influence in lowering the fever heat and diminishing the excited pulse were as marked as its power to relieve pain; apparently because it neutralized the rheumatism-poison, and removed the cause of these disturbances. In the tenth case "*no impression* was made on the disease" for eight days.

The formula used in all these cases is the following:

℞ Acid. salicylic..... ʒ iij.
Sodæ bicarbonat..... ʒ ij.
Glycerine,
Aq.....ãã ʒ ij.
M.

Of this a tablespoonful was given every two hours for the first day, and afterwards the same quantity six times a day. It is not claimed that this is a perfect salicylate of soda. It was prepared rather rudely by the house-physician, not with reference to atomic neutralizing proportions, but by adding the soda to the suspended acid till he obtained a clear solution. It may be atomically correct or it may not; it matters little, as the combination appears to have curative power. This treatment was begun by Dr. Jacobi, and followed up by me. This report does not include any of Dr. Jacobi's cases, but the house-physician informs me that his results were almost exactly parallel with those here noted. It must be added that in both classes of cases, whenever the joints were very painful, compresses, kept cool by frequent dipping in cold water, were applied to them.

Salicylic acid alone is reported to have cured rheumatism; soda alone cures it; and the formula given here might be considered a union of Fuller's with Stryker's treatment, were it not that the urine has not been noticed to be alkaline, and that the quantity usually taken, even if separated from its acid, is hardly enough to produce alkalinity.

In view of nervous symptoms, more or less alarming, that have been reported as following the use of salicylic acid in some cases; (see Dr. Caro's case, MED. RECORD a few weeks ago), it is important to state that no such results have been noticed at the hospital in those who have taken this salicylate; indeed, no unpleasant effects of any kind have been witnessed, though the quantity of the drug administered is large. I will make no comment on the cases, further than to say that in nine of the eleven the curative action of the medicine was early seen; in two this action was slow and incomplete.

CASE I.—John Clark, æt. 24; single; Ireland; waiter. Admitted April 15, 1876. One previous attack, three years ago. Present began five weeks ago, with pain in soles of feet and some swelling; malaise. Left work three weeks ago. Six days before admission, pain and swelling in knees; since in ankles, hips, elbows, shoulders; right wrist and back affected. On admission knees and ankles moderately swollen, hot and tender. Temp. 102½. Ordered the salicylate as above, with cold compresses to painful joints. April 17th, much improved; some muscular tenderness, and pain in left shoulder only remaining. No more symptoms referable to rheumatism developed, and April 26th, eleven days after admission, *discharged cured*.

This patient had a heart murmur whose connection with present attack is very doubtful.

CASE II.—Chas. Quinn, æt. 22; single; United States; kindling wood. Admitted April 19, 1876. Has had gonorrhœa twice, with rheumatism. Had an acute non specific attack six years ago, in this Hospital. On admission for present attack, suffering from pain and swelling in left knee and carpo-metacarpal joint of left thumb. Attack began with chill and sweat yesterday. Mitral systolic and aortic direct murmurs. Some pain in præcordia, no friction. Ordered usual treatment. In 24 hours improvement very marked;

no pain. On April 22d, three days after admission, discharged, very much improved. Duration of attack, four days; duration of treatment, three days; result, cure (?).

Case III.—Wm. H. Welwood; æt. 34; single; United States; horse-dealer. Admitted April 13, 1876. Several previous attacks, subacute in character, with, however, complete recovery. Present attack began eight days ago in right knee, followed soon by pain and swelling in nearly all the joints of body. Was not confined to bed. On admission, left elbow (the only joint much affected) swollen, hot and tender. Temp. 102. Heart normal. Ordered usual treatment. On following day affected joint normal, but stiffness of same joint of opposite side. No further extension or development. On April 17th, four days after admission, discharged cured. Under treatment four days.

Case IV.—H. Heneyer, æt. 30; single; United States; laborer. Admitted April 13, 1876. No history of previous rheumatic attacks. Three days before admission both ankles became swollen, hot and tender. On admission, ankles somewhat swollen and tender. No other joints involved. Temp. 102¼. Heart normal. Ordered usual treatment. On following day much better; some tenderness yet. Temperature normal. Treatment continued; improvement rapid, and on April 24th patient discharged cured. In hospital eleven days.

Case V.—E. Shultze, æt. 28; single; Germany; bartender. Admitted May 3, 1876. Father had rheumatism; died of cardiac disease. History of seven previous attacks; last in this hospital and in this division.

Present attack began six days ago in ankles; swelling, tenderness, and pain, followed by same in all joints of extremities. On admission, wrists swollen and tender, right elbow very tender, and all joints and limbs stiff. Temp. 103½, pulse 103. Mitral regurgitant murmur. Ordered usual treatment. On following day much better; temp., 101°. May 6. Swelling gone; some pain in loins and over heart. May 7. Developed symptoms of alcoholism, and was treated accordingly (pot. bromid., etc.). May 10. Feels all right, except some soreness in two fingers of left hand. May 16. Except stiffness in shoulders, well. May 31. All symptoms absent, except slight stiffness of knees, which disappeared after exercise. Is apparently well. June 5. Discharged cured.

Case VI.—Albert Callender, æt. 27, Sweden; laborer. Admitted May 24, 1876. One previous attack, six or seven years ago; present attack began four days ago, after exposure to wet and cold. Began in toes of right foot, swollen and painful; followed by pain and swelling of ankles. Then knees, shoulders, and thumbs became successively involved. Ankles and knees much swollen this morning. Had two profuse sweats before admission. On admission, above condition found. Ordered usual treatment. Cold locally, there being much pain. May 25. Patient much better. No pain, except a little in knees. May 27. No pain, no swelling. May 29. Discharged cured.

This patient gave a history of dyspnœa on exertion, with frequent spitting of blood, always after exertion. On examination, a mitral obstructive murmur found. Dyspnœa, etc., had existed for four years prior to present attack.

Case VII.—Walter Houseman, æt. 49; single; United States; driver. Admitted May 17, 1876. Brothers and sisters have had "rheumatism." Patient has had numerous attacks like the present. Present attack began one week ago. Shoulder and hand of right side became swollen and tender. On admission, right hand and two middle fingers of same side swollen and red. Little finger much deformed by previous attacks, as also the others, though in less degree. No fever. Ordered usual treatment.

May 20. Swelling in hand much less. Very little pain. Beginning to move fingers.

May 30. Everything gone but deformity, which existed prior to present attack. He is therefore discharged cured. In hospital thirteen days. There was no evidence of gout other than the residual deformity.

Case VIII.—Timothy Rundell, æt. 26; single; Ireland; laborer. Admitted May 23, 1876. No previous attack. Present attack began three days ago in malaise, etc., followed by stiffness on morning of May 21. Stiffness soon followed by severe pain in both knees and ankles, with considerable fever. Left wrist was soon affected and corresponding elbow. Heart has not troubled him. On admission, above joints were found tender and painful on motion; left wrist and left foot somewhat swollen and red. Ordered usual treatment. Temp. on admission, 103¼. May 24. Legs same; left wrist better. Back, right wrist, fingers, and elbow getting stiff and sore. No improvement. Heart normal. May 25. Considerable improvement. All joints of right arm sore but not swollen. Temp., 102°. May 26. Very little pain. Joints weak. May 31. Joints of arms stiff since last note. No more pain. Temp. normal. June 2. Still some stiffness in shoulders. Otherwise well. Treatment continued. June 5. Feels perfectly well; is, therefore, discharged cured. In hospital twelve days.

Case IX.—Ellen Ryan, æt. 48; married; Ireland; domestic. Admitted May 18, 1876. No history of previous attacks. Present attack began three weeks ago in right shoulder. Since then, all joints of extremities have suffered, together with certain muscles. Very little swelling has existed.

On admission, has pain in all joints, but most marked in arms. No swelling of joints except those of right arm, which are swollen and painful. Ordered usual treatment. May 20. Much improved. Right arm and left leg (joints) painful only on motion. Affection finally located in shoulders and persisted. Ordered battery as adjuvant to acid. Preferred discharge to use of battery, and was discharged, May 27, improved. Under treatment nine days.

Case X.—W. H. Higgins, æt. 20; United States; deck hand. Admitted April 14, 1876. No history of previous attack. Present attack began April 1, in right hip; subsequently all the joints. Lower extremities painful and stiff. Left work to day. On admission, is suffering from intense pain in left ankle, which is swollen, hot, and tender. Ordered usual treatment. Improvement in this case was very slow, and no sensible impression made on disease until April 22d, when, with exception of left ankle, symptoms had subsided. Swelling and tenderness persisted here (left ankle), and on May 1, lin. sap. co. and douching ordered. Not much benefit derived from them. Subsequently, tincture of iodine added externally. Slowly improved, and on May 20 was discharged improved.

The acid was continued up to time of discharge.

Under treatment thirty-six days.

Case XI.—H. G. Phelps, æt. 38; England; printer. Admitted April 18, 1876. Has had repeated attacks of subacute rheumatism. Twelve days before admission present attack began in right instep, swollen and tender; subsequently "all the joints of body" became involved. Was in bed one week before admission. On admission, all joints somewhat stiff and sore. Ankles and knees slightly swollen. Heart normal. Usual treatment employed. On following day much better. Continued to improve, and on April 24 was discharged cured. In hospital six days.

October 6, 1874. The same treatment has been continued in the first medical division of the hospital, since the date of the last case, above noted, with no change in the results; except, that in two instances, a certain amount of deafness has been produced, like that which follows full doses of quinine, transient, and in the second case, which I examined yesterday, slight in degree.

A CASE OF CATARRHAL PHTHISIS

WITH ULCERATIONS OF THE LARYNX, SIMULATING ANEURISM OF THE TRANSVERSE PORTION OF THE AORTIC ARCH.

By BEVERLEY ROBINSON, M.D.,

SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL (DEPARTMENT OF THE THROAT), ONE OF THE PHYSICIANS TO CHARITY HOSPITAL, NEW YORK.

The difficulty of accurate diagnosis between cases of phthisis at an advanced stage, and aneurism of the thoracic aorta has been pointed out by almost every writer who has carefully considered diseases of the chest. The clinical separation, however, of symptoms which might appear in a given instance to belong equally well to two entirely different affections, has usually been apparent when one of two conditions existed. 1. A pulsating tumor, with a blowing murmur, present in a region removed from the precordial area. 2. Symptoms due to compression, or involvement of normal structures by a heterogeneous production, and yet neither abnormal pulsation, nor other physical signs of an intra-thoracic tumor to be discovered. With the signs accurately determined of the first division just made, we shall probably find an aneurism of some portion of the aortic arch at the post-mortem examination; with those of the second division, the pathological changes of advanced phthisis are usually evident. There are cases, however, as I am well aware, referred to in text-books and encountered in practice, where phthisis has produced physical signs closely simulating those of an aneurism, and where an error of diagnosis has been made.

Unfortunately, investigation after death of pathological conditions has hitherto rarely given satisfactory proof why such mistakes should be made.

In the case which follows, on the contrary, an example is presented in which the autopsy fully justifies the interpretation made during life of the morbid phenomena then apparent.

Case.—T. F., fifty years of age, laborer, was admitted to Charity Hospital, June 20, 1876. Family history good. For several years past the patient has been troubled with cough and recurring attacks of dyspnœa. He has habits of intemperance. The cough and difficulty of breathing have increased notably within a brief period.

He expectorates abundantly, and has noticed that his voice is hoarse. Sputa are generally white or yellow, sometimes green. His paucity of voice only attracted his attention about one month ago. Patient denies having had syphilis. Upon physical examination of the chest the following signs are discovered:

Just below the left clavicle at its outer third, a distinct enlargement, as compared with the same region of the opposite side, is visible. At the level of this tumefaction there is an unmistakable pulsation. This pulsation appears to be expansive in character, and is certainly much more pronounced than the pulsation caused by the right subclavian artery. It covers an area of at least two inches in diameter.

By auscultation over the swelling described, a murmur of rasping character is readily perceived. This murmur is synchronous with the first sound of the heart, and at the moment it is heard, the head of the observer who listens, is raised up. When the stethoscope is placed over the base of the heart, its sounds are found to be normal. My patient took ninety grains of iodide of potash daily from June 21st to June 23d inclusive. At my afternoon visit on June 23d, I found the abnormal murmur under the left clavicle, as well as the tumor of the same region, decidedly diminished. There could still be no doubt, however, that the left subclavian region was more bulged than the right. Pulsation over tumor was also more limited in extent.

The left carotid artery was beating with considerably less force than the right. No appreciable difference in force or time between the pulsations of the radial arteries. Temperature not taken with thermometer, but there was manifestly some elevation of blood heat. Patient did not complain of any local pain either over the seat of pulsating tumor, or in the left arm. Voice very husky and diminished in strength. Cough almost aphonic. No laryngoscopic examination was made. Respiration performed about equally well on either side of the chest anteriorly or posteriorly. Everywhere there was a quantity of subcrepitant rales and rough breathing. There was moderate dyspnœa. No dysphagia. The iodide was continued at the same dose till June 26th, when patient died in a state of coma, which came on somewhat suddenly. The *autopsy* revealed the following lesions:

Brain in state of post-mortem decomposition.

Larynx presented many of the lesions of an advanced stage of phthisis of this organ.

Lungs.—The following is taken almost verbatim from the post-mortem record, dictated by Dr. Maxwell, Curator at Charity Hospital:

"Patches of old pleuritic adhesions on both sides. Infra-clavicular region of *left* side firmly attached to anterior chest wall. Beneath this a small cavity surrounded by firmly consolidated lung.

"*Both lungs.*—Upper lobes almost completely consolidated by chronic lobular pneumonias, many of them cheesy. Smaller bronchii show intense bronchitis, with a few oval, small ulcerations. Besides these, a few scattered, gray miliary bodies were present. The lower lobes show hypostatic congestion, with some interspersed gray granulations.

"*Heart* dilated, especially on the right side. Walls thin, flabby, and blood-stained; valves normal.

"*Aorta and great vessels at root of neck.*—The latter are normal; in the aorta, about one inch below the origin of left subclavian artery, is a calcareous patch on its anterior surface, the size of a *corn.* (*!*)"

Evidently in the case just reported, the pulsating tumor under the left clavicle was occasioned by compression of the left division of the pulmonary artery by consolidated lung tissue.* On account of the old pleuritic adhesions which attached "the infra-clavicular region of the left side firmly to the anterior chest wall," the soft parts rose and fell in a very exaggerated manner with each systole of the heart. I believe the small patch of atheroma explains in great part the blowing murmur heard during life, although the existence of the pleuritic adhesions at the apex of the left lung, and perhaps also the presence of "a small cavity" in this region, made it louder—or, as it

* It will be remarked that I do not agree with those authors who would explain my case by compression of the subclavian artery, but rather coincide in opinion with those who admit compression of the pulmonary.

were, reinforced it. Although during life a laryngoscopic examination was not made, and the question was then asked whether the loss of voice was due to compression of the left recurrent nerve, or to laryngeal phthisis, I am now fully convinced that, even though I had known loss of voice to be due to local lesions in the vocal organ itself, this knowledge would not have enabled me to avoid a partial error of diagnosis. For, while I would have been more certain in recognizing visually the advanced lesions of laryngeal phthisis, that the post-mortem examination would show the accuracy of my diagnosis, prior to death, of concomitant *pulmonary* phthisis, the aspect of the larynx would not have helped me at all to account for the extensive pulsating tumor of the chest wall otherwise than by admitting the existence of an *aneurism*.

Further, the action of iodide of potash in diminishing the extent of the bulging, helped to confirm me in my mistaken belief, for I wrongly inferred that fibrinous deposits, owing to its influence, were being made in an aneurismal sac.

The fact was, as I at present understand it, that the iodide brought down the arterial tension to a certain degree, and thus decreased the amount of swelling due in great part to transmitted pressure.

Original Lectures.

LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

LECTURE III.

TYPHOID FEVER (CONTINUED).—SYMPTOMS.

GENTLEMEN:—I shall this morning commence the history of the symptoms of typhoid fever.

If I should attempt to give you a correct picture of this disease—one perfect in all its colorings—it would occupy too much time, and you would become so confused as to be unable to recall even the outline of the picture.

After I have briefly spoken of the manner in which this disease makes its advent, I shall consider the prominent symptoms of a typical case of this fever, and then discuss in detail these symptoms, without special regard to the time of their occurrence. This fever usually is insidious in its approach, and comes on with a certain degree of uneasiness throughout the system; the patient feels uncomfortable, has no pain, but feels that he is about to be sick. If the individual is in a region where the disease is prevailing, it is quite common to hear the expression, "I believe I am going to have the fever," and yet those who make such complaint will scarcely admit that they are sick. They complain of a grumbling headache, more or less aching of the limbs, "a tired feeling all over," chilly sensations alternating with flashes of heat; loss of appetite, and not unfrequently nausea and vomiting are present. These premonitory symptoms gradually increasing in severity, by the fifth or sixth day the patient is compelled to take to his bed. At this early period there may be a slight diarrhœa. In very mild cases the disease comes on so insidiously, and with symptoms so mild, that the patient is often able to pursue his ordinary avocations, complaining only of an undefined indisposition—not feeling exactly well, but not regarding himself as really sick. In very many severe cases it is impossible for the patient to accurately fix upon the time when the fever commenced; in no case will you be able to make an early positive diagnosis. Typhoid fever may be suspected, but that is as far as you can safely go.

In all cases variation in temperature is one of the most important early symptoms. These variations in typical cases may be divided into four periods, of one week each, which correspond to the four weeks of the disease.

In the first week there is a gradual and steady rise in temperature, with regular morning and evening variations.

This is one of the characteristic features of the disease. If in any case you find, while making your thermometrical observations, that there is a gradual rise in temperature marked during the first week by regular morning and evening variations, you may be quite certain your patient has typhoid fever. This gradual rise of and these variations in temperature are not present in every case, but when they are present they will greatly assist you in making an early diagnosis.

It has been said that typhoid fever is the only disease, except double quotidian intermittent fever, that gives two full thermometrical curves within twenty-four hours, that is—two full remissions and two exacerbations. If this is true, it helps to explain certain high temperatures in the morning, and affords valuable assistance in making a diagnosis.

During the second week the variations in temperature are slight, retaining, however, the same degree of exacerbation which was reached at the end of the first week.

The variations during the third week are remittent in character.

During the fourth week they become intermittent, and the range of temperature in the exacerbations is gradually lower. The variations in pulse correspond to the variations in temperature. During the first week the pulse gradually becomes more and more frequent, and remains at the height reached, within the first week through the second and third weeks, and falls to its normal standard during the fourth week.

We have thus far briefly considered the ushering in and the early attendant symptoms of typhoid fever. We will now study in detail the prominent phenomena which attend the develoj ment and mark the course of this fever.

The Physiognomy.—As a rule, in the milder cases, the countenance has nothing peculiar in its appearance; the patient does not even look ill. If the disease is of a severe type, by the second week the countenance assumes a characteristic appearance—there is a pale, olive, leaden look, the eye becomes dull and the conjunctiva congested, and usually there is a small, rose-colored spot in the centre of the cheeks. The face does not assume the dark mahogany color, as seen in typhus, but, especially in the latter stages, it has more of the hectic flush of phthisis.

Tongue.—The tongue will also present certain changes. From the very outset it is covered with a light, white coat, but there is nothing special in its appearance before the end of the first week; then it may become red upon its sides and tips, and shows a slight disposition to dryness in its centre. As the disease passes into its second and third weeks, the tongue becomes more heavily coated—the coating becomes brown and dry, and sordes collect upon the teeth and sides of the mouth in sufficient quantities to

form crusts. These crusts may become thicker and more abundant as the disease progresses. At any period in the course of the disease the tongue may suddenly clear off, and present a shiny red appearance, "beef-colored," as it has been called. The tongue and lips may become dry, cracked, and fissured. As the sordes are removed from the lips they will often bleed; and in certain cases, more especially in the severer forms of the disease, the entire mouth and tongue may be covered with dark-colored incrustations. Such incrustations are seen early in connection with those cases where there are extensive blood changes; when present they are of grave significance.

As soon as convalescence is established the changes in the appearance of the tongue are very marked. One of the first indications of convalescence is a moist condition of the tongue about its edges, gradually its entire surface becomes moist, and by the time convalescence is fully established it is restored to its natural condition. Gastric symptoms are always more or less prominent—loss of appetite is one of the earliest symptoms, and nausea and vomiting are quite common during the first week of the fever. The vomited matters usually consist of a greenish fluid. When vomiting comes on late in the fever, it is due to gastric catarrh, or it is symptomatic of local or general peritonitis. In a large proportion of cases the thirst is excessive.

Diarrhœa.—Although not invariably present, it is so frequent an attendant of this fever that it is considered one of its characteristic symptoms. It varies with the severity of the attack, the date of its commencement, and its duration. The characteristic typhoid discharges are of a yellowish green color, described in the books under the term of "pea soup discharges." Sometimes they are of a dark color, resembling coffee-grounds; their reaction is alkaline. In some cases diarrhœa is present at the very outset of the disease, and continues throughout the entire course. In other cases it does not appear until the third week. The second week is the ordinary time for its appearance. When the diarrhœa appears late in the course of the disease, the discharges are more copious than when it appears early. A mild diarrhœa throughout the entire course of the fever is a favorable rather than an unfavorable symptom.

Intestinal Hemorrhage.—Intestinal hemorrhage is not an infrequent attendant upon typhoid fever. It occurs in about one in twenty cases, and varies in quantity from a mere trace of blood in the stools to a profuse discharge of from sixteen to eighteen ounces. The slight hemorrhages which sometimes occur early in the disease simply indicate a hemorrhagic tendency, the same as the epistaxis which is very frequently among the early symptoms. In both instances the bleeding comes from the capillaries of the mucous membrane. The more profuse hemorrhages are due to the opening of an artery in some intestinal ulcer. Hemorrhages due to this cause may be sudden and profuse, and may destroy the life of the patient. The usual time for the occurrence of these profuse intestinal hemorrhages is in the latter part of the second and during the third week. These hemorrhages are usually preceded by a sudden fall in temperature, perhaps two or three degrees; that is, when in a patient severely ill of typhoid fever a sudden fall in temperature occurs during the second or third week, accompanied by extreme prostration, it is very conclusive evidence that intestinal hemorrhage has occurred, although externally the hemorrhage may not have made its appearance. When intestinal hemorrhage occurs during the second or third week it must always be regarded as a grave symptom; yet it is not necessarily followed by fatal results.

Abdominal pain and *tenderness* are not usually present at the very outset of typhoid fever; generally, and almost without exception in the severer cases, by the sixth day of the disease some pain and tenderness will be present in the right iliac fossa. The pain and tenderness usually increases as the disease progresses, and in the advanced stages it is sometimes so marked that slight pressure over this region gives the patient great pain. While examining this region in patients ill of typhoid fever, in order to determine the presence or absence of pain and tenderness, remember never to press the surface with the ends of the fingers, but always make the examination with the palm of the hand; while making the pressure watch the face, and frequently you will be able to determine by the expression of countenance whether you are or are not causing pain, long before an audible complaint is made by the patient.

It is also important for you to bear in mind the possible occurrence of a more severe abdominal pain—namely, that pain arising from intestinal perforation. The following are the characteristic symptoms of this lesion. If in the course of a slight or severe form of this fever, or even when the disease has been latent and the diagnosis of typhoid fever has not been clear, the patient should be suddenly seized with diarrhœa, pain in the abdomen, aggravated by pressure, perhaps at first localized in the right iliac fossa, but soon extending over the entire abdominal cavity, attended by symptoms of great prostration, a rapid, feeble pulse, a sunken, anxious expression of countenance, rapid tympanitic extension of the abdomen, nausea and vomiting, quickly followed by coldness and blueness of the extremities, and the other signs of sudden collapse, you may be almost certain that perforation of the intestines has occurred. I have known this accident to occur when convalescence was progressing safely and satisfactorily. Few live more than thirty-six hours after the occurrence of the perforation.

Tympanitis is another very common symptom of typhoid fever. Usually it is not present during the first week, but by the end of the first or the commencement of the second week a fullness of the abdomen will be noticed. As the fever advances, sometimes the distention often becomes extreme; this is due to a collection of gas in the large intestine, developed from some change in the mucous membrane, the exact nature of which we do not fully understand. We only know that sometimes the mucous membrane of this intestine very rapidly secretes gas, or allows it to generate, and that the intestine becomes distended by its accumulation. When once it is developed it remains until convalescence is fully established. It is always an important diagnostic sign of this fever. In connection with the development of the tympanitis, when firm pressure is made over the right iliac fossa, a gurgling sound is produced, but gurgling in the right iliac fossa cannot by any means be regarded as a positive symptom of typhoid fever, as it may occur in any disease where there is distention of the abdomen due to accumulation of gas in the intestines. In typhoid fever, so long as the abdomen remains tympanitic, no matter what the temperature and pulse of the patient may be, he is in more or less danger, for it shows that there are intestinal changes still in progress, and that the reparative processes are not complete; this is more especially the case when the tympanitis has continued from the active period of the disease

into the period of convalescence. Therefore, the presence of tympanitis during convalescence is never to be lightly regarded.

These are the most important symptoms which are referable to the alimentary tract, and may be regarded as forming, in connection with the temperature variations, the essential part of the history of this fever.

Urine.—Extended and very careful analyses of the changes in the urine of typhoid-fever patients have been frequently made, without giving any very practical results.

Usually during the first two weeks of the fever the urine is diminished in quantity; after the second week it is increased. During the time it is diminished in quantity, its color is dark and its specific gravity is high; when it is increased and convalescence is established, it becomes pale, and its specific gravity is lowered.

The amount of urea excreted daily throughout the active period of the fever is increased. The increase is in proportion to the intensity of the fever, subject in some degree to the quantity and quality of the food taken. It will be greater when large quantities of strong beef-tea are taken, than when the diet consists of milk. So long as the kidneys are able to eliminate the excess of urea, no harm results; but if the quantity exceeds their power of elimination, or if their function of elimination is interfered with, uræmic symptoms will be developed, such as delirium, stupor, and coma.

Albumen in the urine is only of occasional occurrence in the course of typhoid fever. When present the quantity usually is small, and it is only temporarily present. It rarely appears before the third week. Its appearance is often marked by the occurrence of cerebral symptoms. Renal epithelium and casts may or may not be present with the albumen.

Nervous Phenomena.—The symptoms referable to the nervous system are not so prominent in typhoid as in typhus fever; yet there are many cases in which these symptoms play an important part in its history.

One of the most constant of this class of symptoms is headache. In the majority of cases it is one of the ushering-in symptoms of the disease. It is present in mild as well as in severe cases; sometimes it is confined to the forehead and temples, more often it extends over the whole head—not violent, but a dull, heavy pain. It usually increases in severity until the middle period of the disease, certainly until the close of the first week; and generally associated with it there is intolerance of light and conjunctival injection, pain in the back and limbs, and a general ache over the whole body.

Somnolence is another nervous phenomenon, present to a greater or less degree in all cases. In mild cases it does not appear until late, and usually is not long-continued. In the severer cases it appears early and continues until convalescence begins; in fatal cases it increases up to the time when the patient passes into a state of coma. It is often interrupted by delirium.

In children this symptom is especially prominent, and is very valuable as a means of diagnosis. For example, a child complains of feeling sick, without any well-defined pain; upon inquiry you find that he has had little sleep perhaps for two or three days; this fact alone is sufficient indication that typhoid fever will probably be developed.

Delirium is more frequently present than absent in typhoid fever. The character of the delirium varies; the usual form is what is known as the "low-muttering" delirium. This form is rather characteristic of this type of fever, and yet in very many cases the delirium may be violent in character, and may become maniacal to such an extent as to require physical restraint. Not unfrequently typhoid-fever patients attempt to jump out of a window, or to injure themselves or their attendants in their endeavors to escape from fancied pursuers, or are seized with the impression that their attendants are their personal enemies, or that within themselves there is something fearful.

It is very common for the minds of this class of patients to be occupied with those things which engaged their attention just prior to their illness. They imagine about them persons who are absent, and not unfrequently call them in the most endearing tones, or denounce them with the most violent epithets.

The delirium rarely comes on until the second week of the fever, and it commences and is most active at night. After it has once appeared it usually continues until convalescence is established, and generally disappears during a sound sleep which attends the early stage of convalescence. The maniacal form of delirium in typhoid fever is usually most marked at night. During the low-muttering delirium, if the patient is asked questions, generally he will answer correctly.

Muscular Prostration.—This is noticeable in the early stages of typhoid fever in all severe cases, and increases with the progress of the fever. It is generally most marked during the third week. Where there is complete muscular prostration, the urine and fæces are passed involuntarily, there is inability to protrude the tongue, and more or less difficulty in deglutition. These symptoms are often attended with difficulty or inability to articulate distinctly. Retention of the urine, occurring early on account of the inability of the bladder to evacuate itself, is a very unfavorable symptom; the same is true of involuntary discharges from the bowels.

Muscular Tremors.—Tremors of the hands or tongue are most often met with in young subjects, and in those who are addicted to the use of spirits. Severe tremors, unaccompanied by much mental disturbance, often attend extensive intestinal changes.

Spasmodic movements, such as subsultus, hiccough, etc., are early observed in the advanced stage of severe cases. Rigid contraction of the muscles of the neck and those of the extremities are also sometimes present in severe cases.

General convulsions are of very rare occurrence, except in very young children, and when they occur have no special significance.

Special Senses.—The symptoms referable to the special senses require little more than enumeration.

As regards the *sense* of *sight*, there is nothing worthy of note, except that the eye assumes a dull expression and that the pupil is dilated; some patients complain of haziness of vision, which is increased when they assume a sitting posture.

The *sense* of *hearing* is always more or less impaired; this is most marked about the middle period of the fever; then it is impossible for your patient to hear ordinary conversation—you will be obliged almost to shout in his ear.

Ringing and buzzing sounds in the ears are often complained of in the early stage of the fever.

When the loss of hearing is confined to one ear, it is generally caused by ulceration of the mucous lining of the Eustachian tube, or by suppuration of the middle ear.

The *sense* of *taste* usually is altered or perverted; articles of food are tasteless or have an unnatural flavor. When the tongue and mouth are covered with a heavy coating of sordes, with a tremulous tongue, the patient is unable to distinguish between bitter and

sweet, and swallows the most disgusting doses without complaint.

Hyperæsthesia is another disturbance of a special sense. The surface of the body of a typhoid-fever patient may become so sensitive that he will cry out with pain from the slightest touch. This hyperæsthesia may be present during the first week, or may not be present until convalescence is established. It is most marked over the abdomen and lower extremities, and usually occurs in females of a hysterical tendency. It is of importance that you discriminate between cutaneous tenderness in the abdominal region, and the tenderness of peritoneal inflammation.

Epistaxis.—I have already referred to this symptom as of common occurrence in the early stage of typhoid fever. When it occurs during the first week, in most cases it is of little importance, except as a diagnostic sign of this type of fever; when it occurs during the third week it becomes important as an element of prognosis, as it may be sufficiently profuse to destroy the life of the patient. Occurring late in the disease, unless it can be promptly arrested, it always jeopardizes the life of the patient.

Emaciation is perhaps more marked and rapid in this than in any other form of fever. It commences early and is progressive. By the time a patient has reached the fourth week of a typhoid fever of even moderate severity, he is usually in a condition of extreme emaciation. In this particular he markedly differs from a patient ill with typhus fever, for in the latter case emaciation to any great extent does not occur.

Progress of Medical Science.

Radical Cure of Empyema. — Dr. Peltavy, of Mannheim, reports the histories of three desperate cases of empyema, in which the operation of resection of a portion of a rib, first recommended by Roser, produced the happiest results. In the first case, that of a woman 64 years of age, a free incision had been made one month after the disease began; but in spite of all efforts to prevent it, the wound gradually closed, and the patient had hectic and was rapidly becoming exhausted, when resection was decided upon. Exactly one hundred and seventy days after the incision was made, about an inch and a quarter of the seventh rib was resected a little posterior to the axillary line. All the bad symptoms ceased on the next day, and six weeks later the wound had closed and the patient was cured. In the second case, the patient was a woman, 56 years of age, and an incision had been made in the eighth intercostal space back of the axillary line, three weeks after the disease began. The wound, however, rapidly closed, so that but little pus escaped, the fever continued, and perforation of the lung took place. Sixteen days after the incision had been made, a portion of the eighth rib was resected, and in less than two months the wound closed, and the cure was complete. In the third case, the patient, a man 22 years of age, had suffered from empyema a year and a half, and a fistulous opening had existed for a year and a quarter. The opening was enlarged by the knife, and persistent but vain efforts were made during four months to keep the wound sufficiently open to permit of free drainage. Finally, about an inch and a quarter of the sixth rib was resected. In three weeks, the wound had contracted so that a catheter could with difficulty be passed through it, and in six weeks the fistula was closed and the patient permanently cured.

The good effects of this operation do not seem to depend entirely on securing a free outlet for the pus, but partly on the reduction in the size of the cavity produced by the falling in of the ends of the resected rib. After the operation, washing out the cavity and the other necessary manipulations are much less painful, and the patients are consequently more willing to submit to a prolonged treatment. Finally, the operation does away with the necessity for wearing a canula, and the pleura is saved from the irritation consequent on the presence of a foreign body.—*Berliner klin. Wochenschrift*, May 8, 1876.

Treatment of Diabetes Mellitus. — During the last few years Prof. Ebstein, of Göttingen, has treated a number of cases of diabetes mellitus with carbolic acid, with the result of causing a complete disappearance of the diabetic symptoms in a certain number of the cases, while others were entirely unaffected by the remedy. He accounts for this diversity in therapeutic results by a theory that diabetes is symptomatic of different pathological processes that call for different therapeutic measures. The close relationship between carbolic and salicylic acid then induced him to give the latter a trial. In the first case in which he tried it, it was given in small doses, only from five to eight grs. per diem, and produced no effect at all, while twenty-five grs. of carbolic acid caused the disappearance of the diabetic symptoms in four days. The professor, however, now publishes the histories of two cases, in which carbolic acid and other therapeutic measures were utterly useless, one of which was cured and the other greatly benefited by salicylate of soda. In the first case, seventy-five grs. of salicylate of soda were given daily in three doses for eleven days. On one day one hundred and fifty grs. were given, but caused vertigo, noises in the head, and fainting fits. In the second case, one hundred and fifty grs. of salicylate of soda was given in four doses on the first day, but it caused so much humming in the ears, that the quantity was reduced on the next day to three doses of thirty-seven grs. daily. Nine days later, the quantity was increased to forty-five grs. three times daily, and in fifteen days the urine was reduced to the normal quantity, and the sugar to one-third of the quantity passed before the remedy was used. The quantity of salicylate of soda was subsequently reduced to seventy-five grs. daily, and the patient is still under observation. In this case, restriction to a diabetic diet did not seem to aid the action of the drug, and in the first case the cure took place while the patient was allowed a mixed diet, exclusive of potatoes.—*Berliner klin. Wochenschrift*, June 12, 1876.

Action of Salicylic Acid on the Bones.—At the meeting of the *Niederrheinische Gesellschaft* in Bonn on December 6, 1875, Prof. Koster reported the results of his experiments on the action of salicylic acid on the osseous system. Pieces of spongy bone become soft as leather in a few days when placed in a half per cent. solution of salicylic acid, while compact bone tissue is very slowly softened. The enamel of the teeth is very slightly affected by it, but the dentine where it is exposed by caries is rapidly destroyed. Dentists have already recognized the evil effects of salicylic acid on the teeth. The increased amount of the salts of lime in the urine soon after salicylic acid has been taken, shows that the acid deprives living as well as dead bone of its lime salts.

In the discussion that followed, Prof. Binz maintained that the acid is entirely harmless when given for a short time in the proper way. The neutral salt of soda produces the same effects as the acid.—*Berliner klin. Wochenschrift*, July 3, 1876.

Treatment of Phagedenic Sores.—Dr. Weisflog, of Zurich, recommends the electric bath as an unfailing remedy to relieve the pain of phagedenic chancres. One electrode is to be placed in the water, and as soon as the diseased part is submerged, the other electrode, which should be covered with a moistened sponge, is to be gradually seized with two or more fingers, the patient himself regulating the strength of the current by holding the electrode firmly or lightly. Where the bath is unattainable, the nerves running towards the sore should be faradized by means of the sponge electrode. It is important to avoid exciting muscular contractions in the neighborhood of the sore. In the intervals between the baths the sore should be covered with charpie soaked in fat, which the patients generally prefer to all other applications. After the first faradization the pain returns rapidly, but is less severe; gradually, as the electric baths are repeated, the intervals of freedom from pain become longer, until after eight or ten days the pain is not greater than that of an ordinary chancre. The sore itself does not improve under this treatment, but it enables a proper course of local treatment to be carried out.

Of the mercurials, the Doctor prefers the hydrarg. oxydulat. nitricum, which he uses as a salve in the proportion of one to fifty or sixty. It causes slight burning at first, but the floor of the ulcer soon becomes clean, its margins become depressed, and cicatrization advances so rapidly that the entire process is finished in from fourteen to twenty days. The osteocopic pains do not yield much to the faradization, but are greatly relieved by subcutaneous injections of hydrargyrum oxydulatum nitricum in one per cent. solution. This remedy acts well when given subcutaneously; does not, like injections of the sublimate, lead to new gangrenous ulcers; is less painful; produces no abscesses; and introduces into the body a larger quantity of soluble mercury, without exciting salivation. The Doctor uses the injection once in every fourteen days, and as a rule finds that the osteocopic pains are entirely relieved after two months of this treatment.—*Allg. Med. Cent.-Zeitung*, June 17, 1876.

Chylous Ascites produced by Parasites (Hæmatozoa).—Dr. F. Winkel reports the case of a woman, 39 years of age, who had lived long in Surinam, and who, one year after her return to Germany, became affected with ascites, which at first was improved by medical treatment, but later on required paracentesis. About two quarts of a fluid resembling buttermilk were drawn off, in which the microscope revealed the presence of a large number of thread-like, actively moving organisms, $\frac{1}{125}$ in. in length, by $\frac{1}{2500}$ in. in breadth. They had a rounded head with four or five cilia, and a sharp-pointed tail. The patient improved somewhat after the operation, but died soon after without having been seen again by Dr. Winkel. The urine appeared to be normal. Menstration was regular, although the patient suffered from a prolapse of the bladder and womb consequent on the ascites. After the paracentesis a tense, painful swelling of the left leg, and especially of the veins, set in, and lasted for a long time.

Winkel points out the similarity between these entozoa and the filaria discovered by Lewis in chyluria, and thinks that in this case the filaria made their way from the intestinal canal into the lymphatic vessels, and thence into the peritoneal sac. They were probably present in the blood also, and perhaps excited the thrombosis of the veins. The patient stated that a similar affection was not unfrequently met with in Surinam.—*Centralblatt für Medic. Wissenschaften*, June 17th.

The Diagnosis of Progressive Pernicious Anæmia.—Prof. Eichhorst, of Jena, thinks that he has discovered by means of the microscope a certain means of diagnosticating this disease in its earlier stages. The disease is essentially an affection of the red blood-corpuscles, and is as easily recognized as leukæmia. A certain number of the corpuscles are of normal size, and are only noticeable for their remarkable paleness and slight tendency to form into rolls, but others are remarkable for their small size. These latter are often not more than quarter the size of the normal corpuscles, but are more deeply colored, and have lost their biconcave contour more or less completely. Many of them look like small fat-drops, colored red.

The professor has met with seven cases of this disease, in all of which the blood presented the above peculiarities, while they were not found even once in several hundred examinations of the blood of healthy persons and of persons suffering from other diseases, especially such as produced an anæmic or cachectic condition. If the disease in question be observed for a lengthened period, from the earlier to the later stages, the number of these small abnormal elements will be seen to gradually increase, and they may be as numerous as the normal corpuscles. In all his observations the white corpuscles were notably few in number, as were also the small masses of protoplasm which are often met with in healthy blood.—*Centralblatt für Med. Wissenschaften*, June 24.

Dislocation of the Hip.—At the meeting of the *Niederrheinische Gesellschaft* in Bonn, December 20, 1875, Prof. Dontrelepont reported the following case:

About the end of May, a boy seven years of age, met with a traumatic dislocation of the right hip, upwards and backwards. The luxation was not reduced, and when he entered the hospital on August 30th he was unable to stand on the leg; the thigh was strongly flexed, adducted, rotated inwards and shortened, and the head of the femur could be distinctly felt lying on the ileum. Permanent extension and counter-extension were at once applied, and on September 6th the head of the bone was drawn down close to the acetabulum, the shortening was almost overcome, and the flexion, adduction, and internal rotation were very slight. The patient was then anæsthetized, and the thigh was strongly flexed and adducted, and then rotated outwards without force, and the head of the bone slipped into the articular cavity with a snap. Slight inflammatory action followed, but when the case was reported the patient was able to move about, and the movements of the joint were almost normal. Professor Dontrelepont believes that the easy reduction of this dislocation was due to the previous permanent extension, and thinks that in many cases of old luxations that resist the ordinary measures of reduction, the prolonged use of extension and counter-extension will stretch the muscles and ligaments, and make the head of the bone more movable, and so enable the reduction to be made. Even if this fail, the extension will place the thigh in a better position and make the joint more useful.—*Berliner klin. Wochenschrift*, July 31, 1876.

CONCERNING DISCUSSIONS.

THE interest of any subject which may be presented to a society is so much enhanced by the manner in which it is discussed, that we are often surprised that the chairmen do not take more pains to keep the members to their text. The disposition to wander from the subject under discussion has so developed itself by usage and tolerance, that it has become almost one of the distinguishing features of a meeting of medical men. The difficulty seems to be that the right men do not talk at the right time, and that others who are given the talent of loquacity have not enough of modesty to balance their own opportunities with others' interests.

To one accustomed to attend the meetings of medical bodies, it is often amusing to note the great difficulty which the members have in sticking to the point at issue. It should be generally conceded that, if a subject is so entirely new that not even the talking member knew anything of it before the meeting, there was the best possible reason for waiving discussion altogether. Not unfrequently, however, these papers are the most discussed, and give the chronic debaters the best possible chances for saving what they may consider to be the fortunes of the evening.

The desire to discuss a subject at all hazards is one reason why so many side issues are brought in and so much irrelevant matter allowed. The latitude given to the members is sometimes astonishing, considering the distinct purpose for which the meeting is called. We have known, for instance, the discussion of a paper on the pathology of phthisis to terminate or rather dwindle into a reference to the best methods for treating piles. Again, a discussion on the treatment of croup drifted, by curiously unaccountable means, into a canvass of the merits of vaginal syringes. These circumstances certainly cannot excuse the desire which the different chairmen may have for filling up the hour, or apologize to those who lose their time by attendance upon such meetings. We have had enough of these doings, and we hope during the present society season to see some radical change in the ordinary run of society affairs. It seems quite necessary that something should be done to repress the irresponsible and talkative members—in fact, that as far as possible, speakers should be selected who, by special previous preparation, entitle themselves to be heard, and who would give ample satisfaction to all present. Although this arrangement may leave the selection open to the charge of partiality on the part of the chairman, it is still, nevertheless, the only one which under present circumstances is feasible. Of course this would not exclude a participation by others not named in the programme, but would give the discussion a fair start, and hedge in the legitimate premises upon which argument should be founded. If, on the other hand, the subject is merely announced for discussion, the natural modesty of the member who ought to speak is replaced by the alacrity of the one who wants to speak; and the result is some remarks, the greatest merit of which is in their ending. So much depends upon suitable preparation for discussion, that we have known its neglect to spoil the best of papers, and its attention to redeem the most commonplace communications. Let our presidents of medical societies take the hint.

NURSE-TRAINING.

THE value of trained nursing is beyond argument. The main question at the present time is how the object can be best attained. Although the medical profession has long felt the want of competent and trustworthy attendants upon the sick, it is somewhat remarkable that it should have neglected any active means to remedy it. Now that promising movements are inaugurated, with the desired end in view, the next best thing we can do is to give it all possible sympathy and support. So far as we know this has been done, and our good intentions are redeemed by a cordial cöoperation with others who have anticipated us.

The establishment of training schools for nurses is a movement which in this country, particularly, has been attended with marked success. But as yet the beginning is hardly made; and while it proves the good effects of what has been done, it foreshadows the work yet to be accomplished before the full benefits of the system can be realized.

There are now five nurse-training schools in this country, all in active operation and with every promise of future usefulness. With a view of enlarging the benefits which belong to them, and of proposing a more comprehensive plan of organization, a member of the Hospital Committee of the State Charities Aid

Association has recently written a very interesting, suggestive, and elaborate tract * upon the subject.

In the publication in question a very succinct and yet comprehensive history is given of the manner of nursing in the hospitals of the world for the past century, and the different improvements which have been made in this service up to the present. The more we learn of the nursing capabilities of the several institutions named, the more are we impressed with the fact that the want for trained men and women attendants is more and more a necessity. As an offset to this, however, it is a matter of congratulation that not only is this necessity fully realized, but that the proper spirit is being infused into some of the philanthropic ladies of our land to meet it. Being convinced that nurse-training establishments are the only means calculated to accomplish this end, we are ever ready to consider any propositions or plans of organization which may render their good works more general and more effective. We perfectly agree with the writer of the tract that nurse schools should be a part of hospitals, and that the directress or superintendent should have a recognized position in the board of administration. This, of course, is founded upon a presumption, which we believe to be reasonable and just, that the best nurses are females, and that as far as possible the gentler sex should be in the majority. The recommendation that a certain number of ladies should be added to the hospital board may be right enough in principle, but we fear will hardly do in practice. Still, for the sake of the argument, we should be willing to see the experiment tried. The suggestion that the hospital should not only furnish instruction and practice, but board, lodging, and wages for those engaged in the study of their art, is eminently proper, and one which any board of managers can easily see will be in the highest degree advantageous to the interests of their respective institutions. In regard to the details of management there must necessarily be so many modifications, conformably to the different administration of hospitals, that no fixed rule can be followed. The encouragement which hospital committees have given to nurse-training organizations not only proves the general interest in the movement, but promises in the no distant future the realization of a hope that the managers themselves, instead of following the lead of outsiders, will be ready to take the initiative, so that a nurse-training school will be considered as much a part of organization as the medical staff itself. We see no reason why it should not be so—why the hospitals all over our land should not turn out each year a goodly number of skilled nurses, men and women, whose good services would be more than welcomed whenever and wherever they could be obtained. No one could be too strongly in favor of any plan calculated to meet this want, and none who by influence or example can fail to anticipate it more effectually than by giving every encouragement to the nurse-training schools of our midst. Let us throw open our hospital doors and wish them that God-speed which their good work so well deserves.

Reviews and Notices of Books.

MEDICAL AND SURGICAL MEMOIRS. By JOSEPH JONES, M.D. Vol. I., pp. 820. New Orleans, 1876.

PROF. JONES has long since earned for himself the reputation of an indefatigable worker and a pains-taking observer. In the volume before us, which is one of the author's best efforts, we have a remarkable example of what can be accomplished by one individual in the direction of originality and elaboration. One is impressed with the idea that the author loves to write, and is, on this account, inclined to forgive a certain diffuseness of style which amounts almost to tediousness. Still the vast array of facts, historical and otherwise, so amply compensate for the objection of too much detail, that in general the reader will accord to him unqualified praise. Especially will this be the case when the circumstances under which the book has been written are fairly appreciated. Most of the facts of personal observation related, and the experiments given, were elaborated during the late civil war, and were, practically speaking, without any outside aid. The work is remarkable, not only in regard to its originality, but to the wonderful amount of patience and study necessary for its production. The contents of the volume are quite varied, and to the student engaged in investigating all the intricate problems connected with the diseases of which it treats, it is almost invaluable. The bulk of the work is composed of investigations on the nature, causes, relations, and treatment of traumatic tetanus, preceded by an elaborate historical account of the study of nervous diseases in general. All the phenomena of the disease are fully presented from the time lockjaw was first observed and recorded as a distinct affection, down to the present time. As the result of his studies he comes to the conclusion that heightened bodily temperature is only an epi-phenomena, and no indication of a pyrexial state; that the spinal cord alone is not the seat of the disease, but that it often becomes merely the seat of over-exalted functional activity, as the result of peripheral irritation. The pathology of tetanus is presented with a wonderful elaboration as to historical study, but our author is unable to throw any particularly new light upon the subject. His account of experiments with the different so-called specifics are extremely valuable as disproving many of the hap-hazard conclusions which have been arrived at by superficial observers.

The subject of cerebro-spinal meningitis is also treated in this volume, as well as the general history and character of dropsies, and his remarkable experiences in the treatment of pneumonia, so fatally prevalent in the Confederate ranks. Altogether the work is a monument of individual industry and remarkable antiquarian research.

Reports of Societies.

INTERNATIONAL MEDICAL CONGRESS.

SECTION OF MENTAL DISEASES.

The Section met Monday, Sept. 4, at 3 P.M. Dr. John P. Gray, of Utica, Chairman; Dr. Walter Kempster, of Wisconsin, Secretary. The first question was the

MICROSCOPICAL STUDY OF THE BRAIN,

By Walter Kempster, M.D., Supt. Northern Hospital for Insane, Oshkosh, Wisconsin, Reporter.

It was based on microscopical examination of 115 cases of insanity of all common forms, including acute and chronic mania, melancholia, dementia, general paresis, and insanity following epilepsy. He discussed the changes common to the arterioles and capillaries; deposits on the walls of the same; abnormalities consequent on engorgement, the prominent ones being permanent enlargement of the vessels, fusiform dilatations, and miliary aneurisms, occlusion from minute thrombi and embolism, alteration in the course of the vessels, and the effect each condition produces on surrounding tissues. The investing, or perivascular sheath, and the perivascular canal and its contents, were discussed; he had never failed to find both sheath and canal in every case of insanity. In the canal he had frequently found lymphoid bodies which could be made to move about in fresh specimens. His conclusions were, that the canal was a conduit conveying products of water from the cellular elements into the lymph space in the pia mater; the canal existed in the normal brain, and was then more difficult of demonstration. He dwelt on changes observed in nerve cells and their prolongations, and cited the general results recorded by him in a large number of cases of insanity, dwelling particularly on the earlier departure from the normal states. In certain cases examined by him the disease had existed from six days in one case to sixty days in others before death occurred; distinct lesion in the nerve cells could be made out. His conclusion was, that the nerve cells become affected very early in the disease; in certain cases the change preceding the mental alienation.

He regarded the names, "miliary sclerosis" and "colloid degeneration," as unfortunate in not describing the true condition, and being apt to mislead. He has found miliary sclerosis in patches of sclerosis proper or gray degeneration, and the "colloid degeneracy" does not respond to reagents known to affect true colloid tissues. Changes in the neuroglia were described, also abnormalities in the nerve fibres. Finally, he stated the various lesions found in the several forms of insanity; and without asserting that a distinct lesion could be found in each form, he grouped those which he had found common to such, and stated that certain lesions appeared common in the earlier forms, and in the majority of cases were found in the nerve cells.

In conclusion, he showed a number of photo-micrographs on glass, projected on the screen by the lantern, illustrating the changes described.

Dr. Isaac Ray said the paper exhibited great research, and pointed out the way for further profitable investigation. Pathology of the brain had heretofore been unsatisfactory. The scalpel had done its work, and we must rely upon the microscope for further knowledge, notwithstanding certain persons have affected to deride such investigations, but from them we are to derive ideas on causation of disease. He was not ready to endorse every assertion about microscopic changes, or to say that by examining a slice of brain under a microscope we can tell whether a person was insane or not. That time may come, however, and this paper indicates the great advances made in this direction. Examinations in this department should be encouraged in all our institutions.

Dr. Thomas S. Kirkbride said the character of the paper precluded a great deal of discussion, as there were so few who fully understood the subject. He offered a resolution tendering Dr. Kempster their cordial thanks for his paper, and recommending it to the Congress for publication in the Transactions, with the suggestion that the Committee on Publication reproduce as many of the photo-micrographs as may be necessary to illustrate the paper.

Dr. John P. Gray, Chairman, stated that he concurred in what had been said about the paper. In the present state of progression in such investigations we cannot yet reach special conclusions, but may arrive at general results. Certain changes appear to be common in all the forms of insanity; some of them have been observed in forms of nervous disorder, in which the mental status had not been involved; but these facts should stimulate further investigation, as it is the only line left open for further progress.

Dr. Kirkbride's resolution was unanimously adopted.

On Tuesday Dr. Isaac Ray, Reporter, read a paper on the

RESPONSIBILITY OF THE INSANE FOR CRIMINAL ACTS,

setting forth in a very able manner the differences of opinion among jurists and physicians on the question how far insanity should be admitted as an excuse for crime, and he briefly touched upon the opinion of prominent jurists who had discussed this important subject.

Dr. T. S. Kirkbride said that, without committing himself to every assertion made by the writer, the main facts met with his approval, and the ideas should be disseminated; as emanating from this body, the paper will have weight and influence. Dr. Ray's utterances are clear and distinct, and should be made public at this time, when there is a tendency to hold the insane responsible for acts committed when they are insane.

Dr. Clement A. Walker concurred in this paper, which he regarded as a very valuable contribution. To-day there is a reaction against insane people which is growing stronger, especially in Massachusetts, where quite recently the action of the Executive in commuting sentence passed on a person believed by many to be insane, had been received by portions of the community as a direct interference with a proper course of the law, and great feeling has been exhibited. There are some in our specialty who may differ with Dr. Ray on "limited responsibility," but, as a whole, the paper is excellent, and he trusted would receive the endorsement of the Section.

Dr. C. H. Hughes, of St. Louis, did not concur in all the views held by the distinguished author, but approved of the paper as a whole.

Dr. Johnson said he might refrain from endorsing every sentence, but could certainly express an opinion on a subject of so much importance.

Dr. John P. Gray did not endorse the views of the writer as a whole, differing essentially on points involving "limited responsibility," and what the writer called "moral insanity." The conclusions, however, met with his approval.

Resolutions containing the following conclusions were adopted: That there is at present a tendency to hold the insane responsible for criminal acts; that the

tendency is unphilosophical, unjust, and contrary to the teachings of pathology. Therefore, *Resolved*, That the Section endorse the conclusions of the reporter, and present the paper to the General Congress for publication in the Transactions.

On Wednesday Dr. C. H. Hughes, Reporter, read a paper entitled

SIMULATION OF INSANITY BY THE INSANE.

His conclusions were, that it is not only not impossible for the insane to simulate insanity for a purpose in any but its gravest forms of profound, general, mental involvement, but that they actually do simulate acts and forms of insanity for which there exists no pathological warrant that we can discover in the real disease afflicting them.

Dr. Ray reviewed the subject *in extenso*, and referred to the time when insanity, as an excuse for crime, came prominently before the profession. Certain of the insane knew they were insane, and that insanity was an excuse for crime, and when they had committed criminal acts they would simulate to avoid the consequence of the act. It requires no more exercise of the intellectual faculties to simulate than to do many other things which are of daily occurrence. The Reporter had gone fully into the subject, and had clearly explained the views held by the majority of those who have had large experience among the insane. The subject, however, is not as fully understood as it should be by the profession, the members of which are as liable to be called to decide this matter as those who have training in the wards of our hospitals.

The paper was unanimously referred to the General Congress for publication in the Transactions.

THE CHRONIC INSANE.

On Thursday afternoon Dr. C. H. Nichols, of Washington, D. C., Reporter, read a paper entitled "The Best Provision for the Chronic Insane." He reviewed the subject of the provisions made for them, and alluded to the practice in other countries. Communications received from those particularly interested indicated that the provision was inadequate in every State in the Union. It was not possible to expect States to build new hospitals to accommodate all the insane, but very much might be accomplished economically and readily by building on to the structures already erected, thus providing for six or eight hundred in one building, and that they could be attached or removed a short distance from the main structure. The Legislature would be more easily persuaded to provide for the insane in this way than in any other.

Dr. C. A. Walker, of Mass., assented to the propositions, excepting the one advocating increase of numbers above 250 patients in one hospital. He did not think it proper to put 600 or 800 insane in one hospital.

Dr. Ray approved of the paper with the same exception, which he regarded as a fallacy; they could not be cared for more economically in large numbers than in smaller. After four hundred in a hospital all appliances must be increased, and it is a question whether the increased number cannot be more economically provided for in another hospital. The object in establishing the Willard Asylum in New York was to decrease the expense, but their last report shows cost very little below that of other institutions, and everything had been done on what has been called the economical plan, so that there will be constant repairs needed to keep the building whole. Scattering the insane all over a farm in detached buildings or cottages does not lessen the cost of provisions. It is a fallacy to suppose that the labor of the chronic insane can be utilized better from a cottage than from the main structure. The tendency is at present to build cottages, but it did not meet his approval.

Dr. Kirkbride approved of the paper as a whole, but also objected to increasing the number of patients beyond two hundred and fifty, and to the proposition to build detached structures. Cottages were erected many years ago at the Pennsylvania Hospital for the Insane, but they were found impracticable. It was impossible for the Superintendent to give necessary oversight to the insane scattered in cottages over a three or four acre farm.

Dr. Walker offered similar objections. He said that Dr. Jelly, Superintendent of the Retreat at Hartford, did not regard the Appleton buildings recently constructed there as desirable, because they were removed from the main structure.

Dr. J. P. Gray considered the greatest exception to Dr. Nichols' paper was the proposition to erect structures half a mile from the main building. There can be no objection to increasing the number of insane in one hospital, if the staff of medical assistants is proportionately increased. Assistant physicians should be prepared for work in insane hospitals by previous training and experience in general hospitals. With competent medical staff, he saw no objections to hospitals for 600 or 800 patients.

The paper of Dr. Nichols was further discussed by Drs. David D. Richardson, of Philadelphia, Jewett, Kempster, and Hughes. Dr. Nichols made some explanations relative to the proposition to erect separate structures, after which resolutions were adopted, tendering Dr. Nichols thanks for his thoughtful, able, and instructive paper, and recommending it to the Congress for publication, with the approval of the Section, except as to the number of patients most advantageously accommodated in one institution, in respect to which there was some difference of opinion.

CONNECTION OF SYMPTOMS AND LESIONS.

Dr. Edward C. Spitzka, of N. Y., presented a paper "On the Methods of Examination which will reveal a clear and decisive Connection between the Symptoms of Insanity and the Pathological Lesions on which they depend." The paper was illustrated by sections made from an abnormal brain, which were examined under the microscope. The paper was, without discussion, referred to the Committee on Publication. The Section then adjourned *sine die*.

SECTION OF OPHTHALMOLOGY.

This Section was organized Monday, Sept. 4th, with R. Brudenell Carter, Esq., F.R.C.S. of London, as Chairman, and John Green, M.D., of St. Louis, as Secretary.

CAUSTICS AND ASTRINGENTS.

The work of the Section was opened by Professor Henry W. Williams, of Boston, Reporter, on "The Comparative Value of Caustics and Astringents in the Treatment of Diseases of the Conjunctiva, and the best Mode of applying Them." He advocated the employment of the milder class of local remedies as sufficient in all forms of conjunctival disease; some of these affections, those of traumatic origin for example, generally doing best under the use of emollients rather than of astringents. In the phlyctenular form of conjunctivitis only the mildest stimulants were held to be ad-

missible, and of these the reporter expressed a preference for a collyrium of borax (gr. x. to ℥ i.); also touching the conjunctival surface of the upper eyelid lightly with a smooth crayon made from a crystal of alum, in chronic cases.

In the early stages of conjunctival catarrh of moderate severity, bathing the closed eyelids with cool water, and the frequent use of collyria of borax (gr. x. to ℥ i.), or of alum (gr. v. to ℥ i.), or once or twice very lightly touching the palpebral conjunctiva with a polished crayon of sulphate of copper, were recommended as ordinarily sufficient, reserving the somewhat more active employment of the copper crayon, and the use of solutions of nitrate of silver for severer cases of the disease, especially in its chronic forms. In trachoma, he would use the copper crayon in preference to the lapis mitigatus or silver solutions, but without questioning the utility of the latter when skilfully applied. In the acute stage of purulent ophthalmia, especially in the gonorrhœal form, stress was laid on the persistent use of iced compresses, conjoined with extreme care in cleansing the eyes, and frequent use of mild astringent collyria of borax (gr. x. to ℥ i.) alum (gr. v. to ℥ i.) or sulphate of zinc (gr. ss. to ij. to ℥ i.). In the chronic stage, the sulphate of copper crayon was recommended as, on the whole, the best form of astringent. In ophthalmia of new-born children, mild treatment, seasonably begun and faithfully carried out, was advocated almost to the exclusion of other modes of practice.

The following conclusions, being substantially as reported to the Section by Professor Williams, were, after full discussion, unanimously adopted:

1st. In a considerable number of essentially transient affections of the conjunctiva, and in pterygium and other growths, no active treatment, by caustics or astringents, is required.

2d. Where disease affects only a limited portion of the conjunctiva, as in phlyctenular inflammation, the mildest stimulating or astringent remedies are usually sufficient.

3d. In the acute and chronic forms of general conjunctivitis, astringents are, as a rule, safer, as well as more efficacious than caustics, and therefore better adapted to the requirements of the general practitioner.

The discussion revealed a preference on the part of many members for somewhat stronger applications than those advocated by him in ophthalmia of the new-born, viz., nitrate of silver (gr. v., or sometimes gr. x. to ℥ i.) applied over a day, for a few days only, to the everted eyelid, and neutralized by immediately washing it off with salt water. In severe purulent, and especially in gonorrhœal ophthalmia, when attended with great swelling and hardness of the lids, stress was laid on the value of free division of the outer canthus by a single cut with strong scissors, both as a means of relieving pressure on the globe and of abstracting blood.

TUMORS OF THE OPTIC NERVE.

On Tuesday, Sept. 5th, a paper was read by Hermann Knapp, M.D., of New York, Reporter, on this subject. He cited the few cases of optic-nerve tumor contained in recent medical literature, including three under his own observation, two of which had been reported in full in the Archives of Ophthalmology and Otology. These tumors may be of various kinds, and are generally such as afford a hope of more or less permanent benefit from their removal. A prominent feature in the paper was the description already published, of two operations for removal of the tumor without sacrifice of the eyeball, which although blind, may often be preserved, and disfigurement attending its enucleation avoided. The paper of Dr. Knapp, embracing an exhaustive analysis of all the reported cases, was unanimously referred to the Congress, with recommendation to publish.

THE EYES OF SCHOLARS.

A paper was next received from Dr. C. R. Agnew, of New York, entitled "Contributions to the Statistics of the Conditions of the Eyes of Scholars, being a résumé of the Observations of Dr. E. Williams, of Cincinnati, Dr. Wm. Cheatham, of New York, and Drs. J. S. Prout and A. Mathewson, of Brooklyn." The general conclusions from the statistics embraced in it were presented through Dr. Webster, at the meeting of the American Social Science Association, in 1875, but the statistics themselves had never been made public. After much interesting discussion of the causes of the myopia which is clearly shown to develop itself in close relation to the use of the eyes in performance of the work required in our city schools, the Section unanimously recommended to the Congress that the paper be printed, with the statistical tables in full.

ORBITAL ANEURISM AND EXOPHTHALMOS.

On Wednesday, Sept. 6th, a paper on "Orbital aneurismal Disease, and Pulsating Exophthalmia; their Diagnosis and Treatment," was read by E. Williams, M.D., of Cincinnati, Reporter. Several interesting cases were reported in some detail, and one somewhat obscure case of exophthalmos, of traumatic origin, was exhibited to the Section.

Dr. Geo. C. Harlan, of Philadelphia, then presented an abstract of the histories of two cases of pulsating exophthalmos, already published by him, in one of which a cure had followed systematic and long-continued compression of the carotid artery. In the other case, after eight years of uninterrupted progress, severe orbital inflammation occurred during the past year, and ended in suppuration and cure of the disease, but with loss of the eye by corneal ulceration.

Both papers were referred to the Congress with the recommendation to publish them.

ARE CERTAIN AFFECTIONS OF THE EYE HEREDITARY?

On Thursday, Sept. 7th, a paper was read by Edward G. Loring, M.D., of New York, Reporter, on the question, "Are Progressive Myopia and Posterior Staphyloma due to Hereditary Predisposition, or can they be Induced by Defects of Refraction, acting through the Influence of the Ciliary Muscle?" The conclusions reached by him as to the influence of hereditary predisposition in production of myopia were necessarily based on indirect evidence rather than on direct observations, the latter kind of evidence being almost wholly wanting. Comparing statistics published by Erisman in Russia, Max Conrad in Germany, with observations made by Dr. R. H. Derby and the reporter in New York, the conclusion seems irresistible that many cases of original hypermetropia must pass through the stage of emmetropia to become at last cases of myopia. If this conclusion is accepted, we have to assign to the different exciting causes of myopia a preponderance so great as to enable them actually to overpower inherited hypermetropia; and in the presence of active exciting causes of such potency, hereditary predisposition must be held to play a comparatively unimportant part. Inherited weakness of the scleral tunic, which predisposes it to yield to distending causes, is probable, but how important a part it plays in the causation of myopia is not to be determined in the present state of our

knowledge. The conclusion upon this point, as formulated by the reporter, is as follows:

"From the fact that so large a percentage of children are myopic, whose parents are not near-sighted, while the myopia increases directly with the amount of increased tension of the eyes, and from the fact that an interchange of refraction may occur whereby an eye which is not congenitally myopic may become so in spite of hereditary tendency against it, it would seem to follow that hereditary predisposition, though undoubtedly a potent cause, is not only not the sole cause, but it is not even the predominating cause."

In the discussion of this proposition, astigmatism, an extremely frequent complication of high grades of myopia, was cited by Drs. J. Green and Wm. Thomson, as one of the possibly or probably potent exciting causes of myopia, and the importance of more careful determination of the existence of medium and low grades of astigmatism in future examinations of refraction in school children, was insisted on.

The conclusion was unanimously adopted by the Section.

With regard to the question as to whether the ciliary muscle, acting through faulty refraction, can produce myopia and conus, the reporter concludes: "That the action of the muscle, taken by itself, exerts but little influence on the production of myopia, and still less on the formation of the cone."

This second conclusion was debated by Drs. Wm. Thomson, Risley, and Shakespeare, who inclined to the view that the conus is the expression of the effect of the dragging of the radial fibres of the ciliary muscle on the choroid, other members attributing to the strain of accommodation only a secondary influence exerted through the production of hyperæmia leading to hypersecretion and finally to distention of the globe.

This proposition was adopted by the Section, by a vote of fifteen to seven—several members not voting.

REFRACTIVE LESIONS OF THE EYE.

Dr. George T. Stevens, of Albany, N. Y., then read a paper on "The Relations between Corneal Diseases and Refractive Lesions of the Eye." He advanced the interesting view, based on his clinical experience and illustrated by two cases, that refractive lesions predispose to disease of the cornea, and that thus the correction of errors of refraction may be highly important in the treatment of certain chronic or recurrent cases.

This paper was referred to the Congress, with the recommendation to publish.

CYST OF THE IRIS.

A case of cyst of the iris was exhibited to the Section by Dr. Geo. Strawbridge, of Philadelphia.

INSTRUMENTS EXHIBITED.

On Friday, Sept. 8th, Dr. Risley, of Philadelphia, exhibited an instrument for facilitating the investigation of refractive anomalies, and Dr. Shakespeare, of Philadelphia, presented his combined ophthalmoscope and ophthalmometer. Both instruments have been described in the *American Journal of the Medical Sciences* during the past year.

The Section then adjourned *sine die*.

Dr. Alpheus B. Crosby of this city has been elected President of the New Hampshire State Medical Society.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Sept. 21, 1876.

Dr. S. S. Purple, President, in the Chair.

Dr. F. A. Burrall read a paper on

NITRITE OF AMYL AS AN ANTIDOTE TO CHLOROFORM,

in which he brought it forward as the most available of all medical agents to avert the dangerous influence of chloroform when used as an anæsthetic. It was believed that nitrite of amyl acted as an antidote to chloroform by producing a direct paralysis of the vascular walls, hence caused a rapid circulation. Dr. Burrall recapitulated the experiments performed upon cats and dogs by others and himself, and set the amyl down as an agent which should always be in the armamentarium of the medical man who went prepared to meet any emergency that might arise while producing anæsthesia with chloroform. It could be administered from a bottle, or five or six drops might be placed on a handkerchief and held to the nose and mouth of the patient. An exceedingly convenient method of carrying the drug was by means of the nitrite of amyl bulbs suggested by Dr. T. A. McBride, of this city. When required, one of the bulbs could be broken in a handkerchief or towel, and its contents immediately inhaled.

Dr. Gouverneur M. Smith remarked that the question might arise whether the antidote was not a dangerous agent to employ.

Dr. S. Caro seemed to doubt the safety of the antidote in this instance, for the reason that one of his patients, who suffered from angina pectoris and was treated by the use of the nitrite of amyl in drop doses taken by the mouth, fell into a sort of collapse after the fifth dose, which he was quite certain would have proved fatal had not the influence of the drug been arrested by a vigorous administration of aromatic spirits of ammonia.

Dr. J. C. Peters doubted the correctness of the opinion that the collapse in Dr. Caro's case was due to the effect of the amyl, but was inclined to attribute it rather to the prostrating effect produced by the attack of angina.

Remarks were made by Drs. Peters, Taylor, Post, Baylis, Caro, Sell, and Downs

---

NEW YORK COUNTY MEDICAL SOCIETY.

Stated Meeting, Sept. 25, 1876.

Dr. T. Addis Emmet, Vice-President, in the Chair.

Immediately after the nomination of officers, Dr. S. A. Raborg read a paper on

THE INDUCTION OF PREMATURE LABOR IN CONTRACTED PELVES: ITS NECESSITY AND SAFETY IN CASES ASCERTAINED PRIOR TO FULL TERM.

The paper consisted essentially in a report of three cases in which premature labor had been induced, but the interest centered upon the use of the *interrupted current* of hot water (110°F.) by means of a Davidson's syringe, instead of the continued current as obtained in the method of Kiwisch. In the first case the interrupted current was employed, two gallons of water were used each time, and the douche was repeated every three to five hours. Delivery was effected in five days and twelve hours.

The second case occurred in the same woman. The continued current was employed, the same amount of

water used each time, and the douche was repeated at about the same intervals. A Barnes dilator was introduced once. Delivery was effected in nine days and twenty-three hours.

In the third case the interrupted current was employed and delivery effected in five days and eleven and a half hours.

From the above, the doctor believed it was evident that the continuous current could not be relied upon as a sole agent to produce premature labor.

The action of the interrupted current was regarded as a sort of flagellation of the muscular tissue of the uterus produced by throwing against the posterior lip of the cervix a series of jets which would stimulate contraction in the entire organ. The secondary effect of the hot water was held to be stimulating, provoking contraction, as advocated by Dr. T. Addis Emmet. The advantages claimed for the method were that it could not possibly do any injury, and it did not require penetration of the os externum. It required patience on the part of the doctor, and it was assumed that the medical profession was noted in that particular.

In cases where rapid delivery was required, Barnes' dilators were regarded as invaluable.

The paper was received by the Society, and in the discussion that followed,

Dr. Isaac E. Taylor remarked that he had given up the douche as an agent to be used in the induction of premature labor, and knew of no method which could do its work quicker than that by means of Barnes' dilators. They could be used without harm to the mother, and at the same time they were safe for the child.

The discussion was continued by Drs. Caro and White. At its close,

Dr. A. McL. Hamilton exhibited a modification of the gas-jet cautery presented before the American Neurological Association by Dr. Putnam, of Boston (see Medical Record for July 15, 1876, p. 461). Dr. Hamilton has made such modifications as permits the gas to burn without noise, and the instrument can be obtained at a considerably lower figure than the Boston cautery.

The Society then adjourned.

Correspondence.

THE TREATMENT OF ASTHMA.

To the Editor of The Medical Record.

Dear Sir:—In No. 41 of The Medical Record, p. 653, Dr. Beard, among other interesting remarks, says:

"This theory (*i. e.* the nerve theory) led me to recommend central and local galvanization for hay fever before it was known to have been of practical efficacy in this disorder."

Without entering into any discussion as to the priority of advancing both this theory and the galvanic treatment of asthma, I will only mention the following facts. In 1870 I read before the Medical Journal Association a paper on asthma, in which I pointed out the neurotic nature of the phenomena of asthma (a neurosis within the sphere of the pneumogastric nerve), and advocated the galvanic treatment, at the same time giving as practical illustrations several cases of asthma successfully treated by me with the galvanic current. The article was printed in my Galvano-Therapeutics (published by D. Appleton & Co. in 1871, third edition, 1875, p. 140), to which I would refer the reader for further particulars (from p. 128 to p. 155). I may add that since then a considerable number of cases have corroborated my views, though they have led me to some modifications of the treatment, in accordance with the new facts which have accumulated.

Very truly yours,

William B. Neftel.

16 East 48th Street, New York,
October 7, 1876.

THE CAUSE OF CHOREA.

To the Editor of The Medical Record.

Sir:—Dr. G. T. Stevens, of Albany, at a meeting of the New York Academy of Medicine, held June 15th, advanced the theory that "Chorea. . . . arises from irritation dependent upon anomalous refraction of the eye, and in a very large proportion of cases to hypermetropia." I have collected eleven cases of chorea, the refraction of whose eyes has been examined by Dr. C. S. Bull, and the number of cases in which there is no error of refraction will be seen to be six. In seven of these cases there are causes existing which have been held by various authorities to be good and sufficient reasons for the chorea.

Wm. G.....	Hyperopic $\frac{1}{4}$ & Astigmatic.	14	Father a drunkard. In all probability masturbates.
Wm. D.....	Hyperopic $\frac{1}{40}$ to $\frac{1}{25}$.	8	Mother hypermetropic and wears glasses.
Mary E. R..	Hyperopic $\frac{1}{30}$.	12	No history.
Wm. H	Hyperopic $\frac{1}{48}$.	14	No history.
Mary D.....	Hyperopic in L Eye $\frac{1}{25}$ to $\frac{1}{48}$. R. Eye $\frac{1}{20}$ and Astigmatic.	11	Has a functional heart murmur at base.
Nora S.....	No error of refraction.	11	Heart beats very rapidly and has slight murmur, with systole above base.
Frank D.....	No error of refraction.	16	Admits masturbation.
Georgiana M	No error of refraction.	15	Father a drunkard and has an epileptic brother.
Louise R....	No error of refraction.	11	No history.
Albert K....	No error of refraction.	10	Had scarlet fever two months before access of chorea.
Nellie C.....	No error of refraction.	6	No assignable cause.

These cases are not enough to prove that error of refraction is not a frequent cause of chorea, but to show that it is by no means a universal cause. I hope to publish before long a larger number of cases which throw more light on the subject.

R. H. Nevins, M.D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Oct. 1st to Oct. 7th, 1876.

Hartsuff, A., Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 135, Dept. of the Platte, Sept. 30, 1876.

Williams, J. W., Asst. Surgeon. Relieved from duty in Dept. of Dakota, and to report in person to the Surgeon-General at Washington, D. C. S. O. 204, A. G. O., Sept. 30, 1876.

Brown, J. M., Asst. Surgeon. Assigned to duty at Fort Garland, C. T. S. O. 202, Dept. of the Missouri, Sept. 27, 1876.

Gardner, W. H., Asst. Surgeon. Granted leave of absence for four months, with permission to apply for an extension of two months. S. O. 204, C. S., A. G. O.

Buchanan, W. F., Asst. Surgeon. Granted leave of absence for four months. S. O. 206, A. G. O., Oct. 3, 1876.

Tremaine, W. S., Asst. Surgeon. Granted leave of absence for 30 days, upon completion of his examination for promotion. S. O. 202, C. S., Dept. of the Missouri.

Moffatt, P., Asst. Surgeon. Granted leave of absence for four months, with permission to apply for an extension of two months. S. O. 204, C. S., A. G. O.

Dickson, J. M., Asst. Surgeon. Leave of absence extended 15 days. S. O. 104, Mil. Div. of the Missouri, Sept. 28, 1876.

Medical Items and News.

Spiritualism Exposed.—Recently there has been quite a sensation in "spiritualistic circles," by the exposure of a medium fraud in Portland, Maine. Doctors Gerrish and Greene, of Portland, were instrumental in bringing about the issue, and no small credit is due to their audacity and perseverance. The medium in question was a female, who after hiding herself behind a suitable screen in the corner of her parlor, was enabled to send out "spirits" for the inspection of her select audiences. Attired in the ordinary way, she would allow her skirts to be pinned to the floor, and while she was seated upon a stool, the lower portion of the screen being some distance from the floor, the audience were invited to satisfy themselves that the medium did not move from her position. Dr. Greene on one occasion, while the so-called spirit was moving around, asked it to shake hands. This request being granted, he firmly grasped the hand and found the spirit to be the medium herself, who struggled in a very unbecoming way to free herself. While Dr. Greene thus secured the medium, Dr. Gerrish quickly drew the screen aside and discovered the apparel of the lady in a heap at the foot of her stool and still pinned to the floor. The trick was then shown to consist in wearing undergarments, with which she could emerge from her external apparel with ease, and to all outside appearance without any disturbance. But, after all, this is the old story, whenever sensible and brave men are willing to take the pains to solve what would otherwise appear to be a mystery.

Treatment of Diphtheria.—The internal use of chlorate of potash in diphtheria was recommended by Vogel in 1860, in doses of from one-half to three scruples dissolved in water, in the twenty-four hours for children from one to five years of age. Hydrate of chloral was first used as a local application by Ferrini in last year's diphtheria epidemic in Tunis. Dr. Cesare Ciattaglia, of Rome, combines these two methods of treatment, and claims to have had remarkable success with them. He dissolves a drachm of hydrate of chloral in five drachms of glycerine, and applies it to the false membranes three or four times a day by means of a camel's-hair brush. Of the chlorate of potash he gives from two and a half to four drachms a day, dissolved in four and a half ounces of water, to children of from three to six years, and an ounce to adults. With these medicines he always combines a tonic and restorative diet. From the moment the chloral is applied to the false membrane it ceases to spread, and the characteristic fetor from the mouth disappears on the first or second day of its application. The chloral, when dissolved in glycerine, produces less of the burning sensation than when dissolved in water, and also remains longer in contact with the diseased surface. The Doctor gives the histories of eight cases, some of them desperate, that he treated in this way. All of them got well, and in a remarkably short space of time, the remedies being in no case used more than eight days, and in most only five.—*The Lancet*, July 1, 1876.

Poisonous Hams.—In a report recently submitted to the prefect of police of Paris, M. Bouchardat pointed out that in a specimen of ham, said to be imported from Cincinnati, the enveloping cloth was saturated with a yellow substance, that was proved to be composed of the chromate of lead, a most deadly poison. It was suggested in the report that particles of the yellow substance might become detached and be mixed up with the alimentary substances vended by grocers and others, and thus those who make use of them be exposed to the risk of poisoning. By a decree of the police the substances so enveloped were seized and buried under ground, and future supplies are to be treated in a similar manner. M. Bouchardat suggests that if American purveyors prefer to have yellow envelopes around their hams, they substitute for the chromate of lead, any other yellow substance, turmeric, for instance, which is known to be harmless.

New York Aquarium.—A very pleasant reception was given to a large number of the medical profession by W. C. Coup, manager, at the opening of the New York Aquarium on the evening of the 10th inst. The formal exercises consisted of addresses by Hon. R. B, Roosevelt and Prof. W. S. Ward. Dodworth's orchestra discoursed elegant music. A bounteous repast was served, and ardent students of ichthyology were numerous. A reading room and library are attached to the aquarium, and there is also a laboratory, where those who may desire can pursue original investigations regarding the habits and development of the finny tribe.

Sanitary Inspection of English Lodging-Houses.—The Council of the Social Science Association approves of the system of inspection of lodging-houses, but recommends that the measure be voluntary on the part of the proprietors, and that they be allowed to register their establishments as having the certificate of the sanitary authorities.

Original Lectures.

CLINICAL LECTURE ON ACUTE DIARRHŒA.

DELIVERED IN BELLEVUE HOSPITAL,

By W. H. THOMSON, M.D.,

PROF. OF MATERIA MEDICA AND THERAPEUTICS, UNIVERSITY MEDICAL COLLEGE, NEW YORK.

I HAVE chosen the disorders of the alimentary canal as the subject for the present Spring Course of Clinical Lectures, because these affections are so common that young practitioners may naturally expect to begin with them their medical experience, and our remarks to-day will refer to one of the commonest of them all, especially during the coming season, namely, Acute Diarrhœa. Chronic diarrhœa is usually as distinct from acute diarrhœa, both in its nature and in the treatment required for it, as chronic and acute diseases generally are distinct from each other; and hence we must defer its consideration for a future season.

The most frequent forms of acute diarrhœa may be divided, according to my conception of them at least, into two varieties; namely, those due to chemical causes, so to speak, and secondly, those due to nervous derangements. I would class under the first division the diarrhœas caused by acrid fermentative changes in the intestinal contents, which induce in the canal the same kind of drastic action which characterizes the operation of irritant cathartics. The other variety, or choleraic diarrhœa, begins as a painless, watery flux, but may rapidly develop symptoms of the most dangerous vital collapse, and whose interpretation is very difficult upon any theory of mere local intestinal irritation. The leading characters of these two forms, both as regards their etiology and their course, and also, I may add, as regards their treatment, are so different that it is well for us here to begin with discriminating them.

The causes which lead to the development of the first form of acute diarrhœa are generally quite easy to recognize. We should first bear in mind that the digestive juices proper, both gastric and intestinal, are equally endowed with a remarkable property which is necessary to, but at the same time distinct from, their digestive power, and that is, that one and all of them are very efficient antiseptics. Meat, milk, and other putrescible substances, when mixed outside the body with the gastric, pancreatic, or intestinal juices, will not only be acted upon by them, but will also remain without putrefaction or fermentative change for as long time as they will when mixed with some of our best reputed agents for preventing decomposition. When we consider that every morsel of food and each swallow of water, with the air which is mixed with both, must contain multitudes of the germs which induce fermentation or decomposition outside, and that the high temperature of the alimentary canal is peculiarly fitted for their development, it becomes plain that nothing but a free and constant supply of antiseptic agents can prevent the speedy occurrence of putrefactive processes. Were the gastric juice never so active as a solvent, yet this would avail little against the poisonous changes which the food would undergo ere there was time for the secretions of the stomach to complete their share of the work, and this difficulty of course would progressively increase with every foot of the tube beyond. The first effect, therefore, noticeable upon a suspension or a perversion of the digestive secretions, from whatever cause, is fermentation or decomposition of the contents of the canal. Lactic, acetic, and butyric acids, sulphuretted hydrogen, and ammonia, and other gases are formed, with the result of producing the most irritating mixtures that can well be imagined, and whose caustic action is manifested in the inflamed throat, nose, and lips, and the running tears which accompany their ejection by vomiting, or the excoriations about the anus when these matters are voided. This one consideration, that the antiseptic property of the solvent secretions is quite as necessary as their digestive power, and hence, that the absence of these secretions is dangerous, aside altogether from the danger of starvation, affords a very fair explanation of many troublesome fluxes which we meet in disease. The diarrhœa of typhoid fever and of phthisis, for instance, are not by any means due solely to a specific affection of the intestinal glands, because any rise of the blood heat is a cause of arrested or of diminished secretion, whether from the skin outside, to the kidneys, or the intestines inside; and let the fever-heat last long enough, and you may have the intestine bathed with decomposing irritating fluids, and "a colliquative" diarrhœa set in which differs in no respect from the flux of typhoid.

The symptoms of this form of diarrhœa are but the signs which the intestine must give under the circumstances. A great serous flow takes place to dilute the irritating fluid, just as acid in the mouth causes an abundant flow of saliva. Then comes a sense of uneasiness, followed by diffused soreness through the bowels, and soon some portion of the intestine becomes cramped in its hurried peristalsis. The patient feels the same as if he had taken a griping dose of colocynth or gamboge, and ere long he has an evacuation with a burning sensation, a discharge of flatus, and a sour or putrefactive odor, which show nothing so much as that for some hours or days he has not had enough gastric or intestinal juices for the proper change of the food, and hence it has changed into an intolerable cathartic. Those persons who become greatly prostrated or faint by medicinal cathartics are prostrated in just the same way by a single evacuation of a simple summer diarrhœa, and it is very common, on the other hand, to find some persons as much benefited by a purge compounded of acetic, butyric acids, etc., as by a well-mixed laxative from the apothecary. Their "biliousness" and muscular languor or pains go off, and they feel as much relieved by the one as by the other.

If a brief flux of this kind would in every case not only bring away the decomposed intestinal contents, but also remove the causes which primarily suspended or perverted the natural secretions, then there would be no need for treating this form of acute diarrhœa at all. But very often the original disturbing cause with the secretions continues to operate. The contents of the intestine, whether ingesta by the mouth or secretions from the blood (for the daily flow into the intestine of secretions has been estimated as equal to the mass of the blood itself), continue to decompose, and therefore, to renew the purging at shorter and shorter intervals, until inflammation or even ulceration result locally, and systemic depression generally. The patient, if he had ideas at first of a looseness of the bowels being a beneficial process of riddance from surplus bile, begins to wish to have it stopped. It is then that you should be in the best position to judge. The indications for arresting the flux are often urgent. We have quite a number of remedies which can directly restrain excessive intestinal discharges, and

often the sooner the bowels are "locked up" by them, the better. But on the other hand, this locking up is as often a mischievous practice. You only check, as by an insufficient dam, the flow, to have it break out again more uncontrollable than ever. The decision here as to the best course to pursue is generally very perplexing to the physician with his first patient. It is now, therefore, that a careful consideration of the causation and the nature of the diarrhœa has so much to do with the management of the flux, for success will depend more upon a proper judgment of how the trouble began rather than how it happens to continue.

Take, for example, the diarrhœa common with teething children. I have often suffered from toothache myself, with the invariable result of finding that an aching tooth can seriously disturb the stomach. It is not the pain alone which takes away the appetite, furs the tongue and brings on a qualmish dyspepsia, for the divisions of the trigeminus are allied through more than one branch with the gastric nerves, so that not only a frontal headache accompanies an irritated gastric mucous membrane, but, vice versa, a painful tooth will often in adults check the flow from the follicles in the stomach. It would seem, therefore, that we may infer correctly that the reflex irritation produced by one or by several teeth pushing their way through the narrow bony bed in the undeveloped jaw of infancy, may be severe enough to suspend the gastric secretion almost completely. Should this occur, the milk will soon be vomited with a very sour smell, and simultaneously with this symptom, you have plain evidence that something is producing pain and disturbance in the bowels. Irregularities of the local temperature, the unfailing signs of radiated intestinal irritation, first manifest themselves. The feet and hands turn cold and contract, the head becomes hot and the face streaked, and soon the vomiting is succeeded by an evacuation which has the same kind of fermented odor which is perceptible in the matter ejected from the stomach. There are other characters besides the odor to be noted in the passages similar to what comes from the stomach, such as the collections of undigested casein, but we would direct special attention to the sour smell for this reason. The gastric juice is itself acid, and hence, some may think that the taking of mineral acids to relieve the dyspepsia of a sour stomach, or to act as astringents in diarrhœa, is somewhat after the Hahnemannic principle; but in reality it is just the reverse. Though the gastric juice is normally acid, nothing that it is mixed with should *smell* sour; that is a certain indication of fermentative change caused by the deficiency, and not by the excess, of the proper acid. On the other hand the intestinal juice is alkaline, but still as effectual a preventive of fermentation as is the gastric juice, so that sourness of the digester is equally an evidence of a great deficiency in the normal secretions of the bowels, and due to the same cause, namely, arrest, through reflex irritation, of the functions of the digestive glands. The way to treat such a diarrhœa, therefore, will differ in several respects from the treatment of almost any case of diarrhœa in adults. The first thing to do is to put a stop to the nerve irritation, and for this purpose we may adopt several different procedures. One of the oldest and most familiar is scarification of the gums, an excellent measure if done when needed, and that is, only when there is hyperæmia of the gums. If they are swollen and hot, a few drops drawn from them by the prick of a lancet, relieves them greatly, on the principle that local bloodletting is one of the most effective vascular and nervous sedatives that we know of. We are utterly without an explanation of this fact, but the child is quieted in just the same way that the dreadful spasmodic dyspnœa of a thoracic aneurism is sometimes marvellously quieted by the trivial bleeding from two or three leeches applied at the top of the sternum, or the pain of pericarditis by the same at the precordium, or the irritable stomach in acute hepatitis by the same at the epigastrium, or the headache of meningitis, by the same applied to the mastoid processes. There is no support afforded by these clinical facts to the advocates of general bleeding, for the amount of blood taken in the case of aneurism, for instance, is too little to produce the slightest change in the sac or in its contents. But the cases where lancing the gums is called for are comparatively few. We should remember that the greatest aching usually accompanies the growing of the teeth through the bony canal, before they begin to encroach upon or irritate the gums at all, and hence, if the gums are neither red nor tumefied, you had better not attempt the operation, for it will be of little avail. The laity, and some physicians even, imagine that cutting the gums is for the purpose of making a way for the teeth to grow out; but a young gentleman, ambitious for a moustache, might as well prick holes in his upper lip to help the hairs appear, as the practitioner to think that a soft mucous membrane can really delay a growing tooth.

We have, however, in the bromide of potassium an agent which possesses an incontestable power of arresting reflex irritability. Its free administration lessens even normal reflex movements, as in winking; and if you are annoyed with excessive excitability in the fauces of patients whom you wish to examine with the laryngoscope, you can generally soon obviate this by giving half a drachm of the bromide. While the more the reflex irritability is morbid in its degree, the more effective will this agent be found. It is not an anodyne in the usual sense of that term, for I doubt if it relieves pain at all; but it certainly can prevent, by its paralyzing effects upon reflex processes, the toothache from disturbing travels to distant nerve distributions. Whether this theory, however, be correct or not, I nevertheless believe that I have found this drug exert a positive remedial action in the diarrhœa of dentition, given in five-grain doses every three hours or so, and my only explanation therefor is, that the gastric secretory nerves are allowed by it to return to their own business through its freeing them from the influence of the dental irritation. I need only mention also, that it is of special use in those numerous cases where slight irritations are apt to induce infantile convulsions or spasmodic croup. Another effective agent for calming the nervous symptoms, and thus restoring the stomach and bowels, is cold to the head. I have found the employment of Potters' hydrostatic bag, filled with enough ice-water to make a comfortable cushion for the child's head, act as nicely in checking restlessness and inducing sleep, as the most approved medicinal prescription. Cold water applied to the head directly, is objectionable for many reasons, so that if you cannot procure a water-tight receptacle like the one just mentioned, I would recommend your adjusting bottles of ice-water about the head, which should be protected first by a thin napkin or handkerchief. When you take into consideration the great disproportionate development of the brain and the nervous system in children, you will readily perceive the need there is for early attention to the deranged central circulation which is so apt to supervene in them, and which soon of itself must react upon the gastric and intestinal disorder. The paralyzing effect on reflex action of immersion in warm water is doubt-

less also the explanation of the benefits found from the use of the warm bath in these cases.

I am, however, in these remarks, anticipating the fulfilment of one indication which in most instances should take the precedence of all the rest. If you were called to treat a case of poisoning by some irritant, you would think first of freeing the stomach or bowels as soon as possible of the material which is inflaming the mucous surface, before you would administer anything else. But food once fermented in the alimentary canal is unfit to stay there a moment beyond it is possible to get rid of it, because it not only acts as a local irritant, but by its presence it arrests any proper digestion of matters taken subsequently, as it induces fermentation in them also. The reason why even the briefest attack of the kind seems to tell so quickly upon the muscular tone, the color and the strength of the little patients, is doubtless because, for the time being, all real feeding is arrested. The alimentary canal appears to stop renewing the supply at once, and after one day's continuance of the trouble, as great a change manifests itself in the child's condition as if it had been actually deprived of nourishment for the same number of hours. I have, therefore, never seen cause to regret my beginning the treatment of such cases with the nursery remedy of castor-oil, though I have seen cause to regret not doing so from a mistaken confidence in the previous purging having disposed sufficiently of the offending matters. We are apt to be too much influenced by the activity of the diarrhœa towards stopping the flux at once, lest it exhaust the patient. But it is scarcely possible to irritate the patient's bowels with the oil, however given, in comparison with the irritation which fermented cheese is capable of producing; and so often will the whole trouble promptly subside after a single good operation by this medicine, that I am inclined to recommend your beginning the treatment of infantile diarrhœa with it very much as a routine prescription. After it has acted, you may rely on your other measures with much more confidence than you have reason to entertain without it.

Another indication, present from first to last in the course of the complaint, is to supply the deficiency of the gastric juice by artificial substitutes. You cannot do any harm by pepsin and a few drops of muriatic acid; but you may be doing thereby just what is needed to prevent a repetition of the abnormal change in the food; and when there is much gastric irritability, the common addition of bismuth to pepsin is certainly indicated. As the friends generally dread too many prescriptions, and we are being constantly warned by a public, which many of our own teachers labor to inform, that it has been greatly overdosed by our unenlightened predecessors, you had better say that pepsin is no "medicine" at all, but a help to digestion derived from calf's or pig's stomach. The derangement of the digestive processes of course demands also that for a time the stomach be allowed to do less work. The heat of the mouth and fauces (especially after vomiting) increases thirst, on the other hand, so much that the child is likely to be nursed or fed altogether too often. Drinks of cold barley or rice water therefore, in spoonful doses, or equal parts of cold milk and lime water, are very properly recommended in your text-books, for the reason that with no real appetite, the patient should be relieved with drinks which will tax the stomach the least; otherwise, your best prescriptions may wholly fail.

Should you now find, say on the second day after beginning with the measures recommended so far, that the diarrhœa continues, and that the discharges are more watery or frequent, I would then begin with a combination of familiar correctives which I have found best administered in the form of a prescription given by Dr. West in his book on children's diseases. I will have something more to say on the action of rhubarb with alkalies in the diarrhœa of adults, but I may remark, that having once held the children's class in one of our city dispensaries, I made and recorded the results of comparative trials of various reported prescriptions for diarrhœa. The attendance during the hot months became inconveniently large, and I adopted the plan of giving the patients alternately as they came in, West's rhubarb mixture, and one or other of the usual mixtures containing sulphuric acid and laudanum, chalk mixture, ipecacuanha or astringents, notes being taken of each, and a promise exacted to report again. After six weeks' experience, the superiority of the rhubarb prescription appeared to me so certainly demonstrated that it has influenced me in treating summer diarrhœa in young and old ever since. West's prescription is this: ℞ Magnes. Sulph., ℥ i.; Tr. Rhei. ℥ ij.; Syr. Zingiberis, ℥ i.; Aq. Menthæ, ℥ ix. M. ℥ i. ter die for children a year old. You will note that there is no opiate in this mixture, and you should bear this in mind, for if you can check a diarrhœa of this kind without this drug, by all means try to do so. Instead of thinking of opium first, always think of it last, when the bowel trouble has maldigestion as its beginning, because opium is invariably a hindrance in children to the proper secretion of digestive juices. The indication for opium arises only when the discharges not only continue profuse, but also are evacuated with a suddenness which betokens excessive peristaltic action. In such a case the addition of a drop of laudanum to each dose of this mixture will generally suffice, for I prefer to give the sedative only in this combination, as the one least calculated to neutralize its interference with the digestive secretions.

(To be continued.)

Original Communications.

THE RELATION AND HEREDITARY TENDENCY BETWEEN INEBRIETY AND EPILEPSY.

By EDWARD C. MANN, M.D.,

MEDICAL SUPERINTENDENT STATE EMIGRANT INSANE ASYLUM, WARD'S ISLAND, NEW YORK.

(Read before the meeting of the "American Association for the Cure of Inebriates," held at Philadelphia, Sept. 26, 1876.)

Very little attention has yet been paid to the relation and hereditary tendency existing between inebriety and epilepsy, although a very close relation undoubtedly exists between them. Careful examination reveals a large number of persons affected with epilepsy whose parents or ancestors have been addicted to intemperance. There is a very close analogy existing between the paroxysms of a dipsomaniac, where there is often a prodromic stage of nervous disturbance which may incapacitate the patient for mental labor, and the convulsions of an epileptic, whose paroxysms of intense nervous excitement are generally preceded by the "aura epileptica;" the difference being that in the former case the paroxysm lasts for weeks perhaps, while in the case of the epileptic it lasts but a few moments. As we often see the two diseases existing in the same person, it becomes impossible not to

infer a similarity of origin. We have in both instances accumulated and pent-up nervous force or irritation, which finally expends itself, in the one case in the unrestrained indulgence, in the irresistible impulse to indulge in alcoholic stimulants, and in the other in the convulsive movements of epilepsy. There would seem beyond all doubt to be a correlation of force which results in the mutual convertibility of these two diseases. It is not an unusual case to find in the various members of different generations of the same family different phases of the neuroses, such as insanity, epilepsy, phthisis, chorea, or inebriety, showing beyond all doubt correlation of morbific force in hereditary diseases. I believe most firmly that the morbid condition of nerve element, or morbific force induced by inebriety, is indelibly impressed upon or is transmitted to the ovum at the time of conception, and that this morbific force lies dormant in the system until developed by an adequate exciting cause, and that the hereditary neurosis thus often skips a generation, leaving no appreciable manifestation of its existence in the intermediate generation. When this morbific force *does* manifest itself, next to the transmission of the predisposition to inebriety comes unquestionably epilepsy. From my experience, the children or grandchildren, while infants, are generally affected with convulsions, which may prove fatal, but more often tend to assume an epileptiform type, as the child advances in years. I have repeatedly noticed, in patients who did not have complete epileptic seizures, *epileptic vertigo*, which passed off almost instantly, but which for the time evidently abolished consciousness partially if not entirely. The brain of such children is often morbidly active, and too high pressure in education, or an unnatural forcing process during the formation period of childhood, often results, especially in girls, during the period of constitutional evolution—a time at which the organism is under physiological conditions that predispose to pathological states—in disturbances primarily of the organs of respiration, circulation, and digestion; and secondarily, in the production of hysteria and epilepsy by over-stimulating a brain already morbidly active and predisposed to disease, upon the application of even comparatively trifling exciting causes. Again, consanguineous marriages may be the connecting link between inebriety and epilepsy. I have known cases in which the intermarriage of blood relations, where there was inebriety that had lain dormant for one or two generations, has resulted in the old hereditary neurosis reappearing in the form of epilepsy in the offspring. It is a curious fact, also, that the sons born as the result of the union of cousins in marriage appear to have a strong tendency toward inebriety. The only explanation which I can offer of such cases is, that it is probably the development of the latent morbific force residing in the constitution of the parents, who have a common ancestor, which has been lying dormant for one or two generations, and which is developed in the offspring as the result of the consanguineous marriage. I think that such latent morbific force and hereditary disease is far more common than we generally suppose, and that in many cases both insanity and inebriety are only the expression of latent disease, elicited by external, accidental causes, rather than as the result of moral or physical causes, to which they are attributed both by the laity and by the profession.

The epileptic convulsions occurring as the result of inebriety depend mainly, I think, upon a two-fold cause, which operates in the production of a morbid irritability of the medulla oblongata. Whether this be a transitory or a constant state, I think, is an open question. I am inclined to think that it is a *constant* state, which may, however, for the production of the epileptic paroxysm, require the additional stimulus of transitory cerebral irritation to be transmitted to the medulla oblongata, and perhaps the sympathetic. The two-fold cause which has appeared to me to operate in the production of what I take leave to term *alcoholic epilepsy*, consists, first, in hyperæmia of the brain, which causes symptoms of irritation due to increased excitability of the nerve filaments and ganglion cells of the brain, which, by transmitting to the medulla oblongata a morbid irritability, results in epileptiform convulsions. Second, a state of cerebral anæmia which also induces a morbid irritability of the medulla by causing arterial anæmia. Finally, I believe that as a result of inebriety we may have epileptic convulsions occurring merely from the state of nervous irritation produced in the medulla and at the base of the brain, which excites the motor nerves, from the poisonous and improper character of the blood plasma produced by the presence in it of alcohol. This I believe is often the case without either very marked anæmia or hyperæmia of the brain. This appears reasonable when we reflect upon the fact that the amount of blood going to the brain constitutes about one-fifth of the whole bulk of the blood. Consequently any poisonous or injurious change in the condition of the usual supply of blood must be very apparent in the encephalic condition, and produces cerebral irritation incompatible with the performance of healthy function.

There is in epilepsy, and more especially in epileptic insanity, a period which sometimes precedes and sometimes follows the epileptic paroxysm, in which often occurs an abrupt and complete change in the moral nature, so that we often witness the change from a sober, honest, and industrious to a dissipated, negligent, and lazy man. These attacks often recur periodically in the course of epilepsy, associated with more or less maniacal excitement. During these periods of moral alienation there has often occurred in patients under my charge an irresistible desire to indulge in alcoholic stimulants to excess, so that for the time the patient, if not restrained, would pursue a course of inebriety, his reason seeming powerless to control the temporary dipsomania. There is still another class of cases in which the moral insanity takes the place of the epilepsy or epileptic mania, as the case may be; and these cases are also very prone, according to my experience, to be addicted to inebriety, if the opportunity of gratifying their morbid impulse occurs. In my observations, and in my study of insanity, I am continually called upon to witness its connection with disease, and more particularly with the hereditary diseases; and I have come to believe, as I have endeavored to show, that inebriety and epilepsy are mutually convertible diseases. They both depend upon the morbific force before alluded to, which may remain latent in the nervous system for a long time between the intervals of its manifestation; and although there is a certain dissimilarity of the symptoms between the two diseases, it does not at all follow that they are owing to different causes. The fact of the hereditary disease appearing in different forms in members of the same family, and passing from one form to another, leads us to positively infer a correlation of morbific force which leads to this mutual convertibility, which includes not only inebriety and epilepsy, but also, I think, phthisis, skin disease, insanity, and scrofula, and perhaps rheumatism and gout. In my asylum practice I have had ample proof of this, in the existence of the different phases of hereditary disease

and their alternations, both in the same individual and in various members of different generations of the same family. With regard to the treatment of hereditary diseases, which I do not propose to take up in this paper, the chief indications, I think, point to hygiene and to wise marriages. As we have seen that the symptoms of constitutional disease are manifested soon after birth in convulsions or some affection of the nervous system, we must turn our attention to the nourishment and education of the child, and endeavor to exclude everything prejudicial to its future mental and bodily health. By such attention to hygienic rules are we, as physicians, to endeavor to secure an exemption in the rising generation from these hereditary diseases, so far as we may; and it is certainly our duty to aim at the eradication and stamping out of hereditary disease, which, if it is accomplished in the future, as we hope it may be, will complete the entire round of the possibilities of preventive medicine.

Epilepsy occurring in offspring as the result of inebriety in the progenitors is complicated with defects or disorders of the mind in various ways, and the manifestations may with propriety, I think, be classified as follows: 1st, epileptic idiots whose intellectual faculties have never been developed; 2d, epileptics who are imbecile or demented; 3d, epileptic maniacs, who, without obvious disorder of the mind, when epileptic fits are coming on, are irritable, morose, malicious, and dangerous, and sometimes perpetrate fearful crimes. In some instances the mental disorder takes the form of a paroxysm of acute mania, coming on suddenly. 4th. Epileptics whose intellects are not impaired.

Pathology.—The pathology of the production of epilepsy in the offspring of intemperate parents is very obscure. The condition of the mother during gestation, if abnormal, as in inebriety, cannot fail to interfere with the proper nutrition of the cerebral tissue of the fœtus; and it is in this way, I think, that during embryo life the brain of the infant often undergoes pathological changes, which induce both deficient moral power and epilepsy. It is certain that any pathological state which destroys the equilibrium of the functions of the organs of the mind, producing depression of some functions and excitement of others, cannot fail to produce in the children of such parents an ill-balanced and defective state of the nervous system, disposed to take on diseased action. It is probable that there exists in such children a state of the cerebral vessels which interferes with the uniform and healthy interchange of nutritive plasma, passing from the vessels to the brain cells, and of the fluid cell contents in a state of degenerative metamorphosis, passing from the brain cells to the vessels. This state of the cerebral capillaries induces a morbid activity of the cerebral cells, which is in all probability the determining cause of the epileptiform convulsions from which such children suffer. That the functional disturbance resulting in epileptiform convulsions in such children may be due to diverse causes—that is, to anæmia as well as hyperæmia—I have proved to be a fact, as I have found in two or three instances the brain and membranes completely bloodless in children who died in hospital in the midst of convulsions, although I think that the general rule in such cases is more often to find an excessive quantity of blood present.

After numerous dissections of the brains of epileptics, both in cases resulting from intemperance and in cases occurring under ordinary conditions, Foville and Andral agree in their testimony that there is no special lesion attending this malady. Andral insists upon the necessity of distinguishing between those cases in which death occurs in the interval and those in which the patient dies in a fit, as in the latter class of cases there will be congestion of the cerebral vessels, which is the effect and not the cause of the fit, as some might suppose. I have found that among the cases coming under my charge in which inebriety in the ancestors could be clearly traced as a predisposing cause, very few, if any, of the patients had been healthy persons previous to the accession of the disease. That in a great many instances, especially in women, hysteria and other nervous affections had existed previously, and that functional derangements of the nervous system had been of frequent occurrence since infancy. The pathological appearances which have been found by Schroeder van der Kolk in the medulla oblongata would seem to show that epileptic convulsions depend generally upon an increased afflux of blood to the medulla oblongata; although, as I have previously stated, it is a fact which has been proved by Küssmaul's and Tenner's experiments, by cutting off the arterial blood from the brain, that arterial anæmia is also a cause of epilepsy. Schroeder van der Kolk found that in the medulla there generally existed a dilatation of the arterioles and capillary vessels, with thickening of their coats. In the cases where arterial anæmia of the medulla is the cause of the epileptic convulsion, it is probably the effect—when it occurs in the inebriate—which the alcohol exerts in producing a transitory spasm of the muscular fibres of the arteries, with consequent arterial anæmia.

Prognosis.—In epilepsy occurring in the inebriate himself, as the result of the morbid irritability produced in the central nervous system by his excessive drunkenness, we may reasonably expect an ultimate cure if there is no structural change in the brain which has resulted from the course of inebriety. I have had three such cases of recovery in patients under my charge. On the other hand, when the disease occurs in the offspring of intemperate ancestors as the result of the hereditary tendency, it depends more certainly upon structural disease of the brain; and, as a general rule, the more frequent the recurrence of the epileptic convulsions in such patients, and the deeper the impression which they leave behind them, the less hope do I entertain of ultimate recovery.

OBSERVATIONS ON THE PHYSIOLOGY OF MENSTRUATION; WITH NOTES OF A CASE IN POINT.

By JOSEPH WORSTER, M.D.,

NEW YORK.

The contributions of Dr. Kraus, of Vienna (Austria), to the physiology of the prostate gland, afford such decided evidence of the importance of normal function of that organ to sexual competence, and establish such an undoubted homology between the sexual processes of the male and female, as indicated by the observations I shall presently describe, that I am emboldened to give a summary of his conclusions before entering upon subject matter of my own. The points established by Dr. Kraus are:

1. As long as the seminal fluid remains within the testes, vesicles, and other seminal passages, it is colorless, scentless, and has an appearance very similar to that of fresh honey while deposited in the comb. In this state its reactions are neutral.

2. It is only after it has quitted the passages and

arrived in the urethra that it acquires its white color and its peculiar faint smell.

3. During its passage through the prostatic portion of the urethra the prostate gland pours out its fluid, which colors the semen white, and confers upon it the property of coagulating on exposure to the atmosphere. As would be inferred from the last statement its reaction is now alkaline. On the other hand, semen taken from the vesicles is not subject to coagulation on exposure to the air, but continues transparent, colorless, and odorless.

4. In the absence of the prostatic fluid, the spermatozoa of the mammalia cannot live in the mucous membrane of the mammalian womb; but, with its assistance, they may retain their vitality for from thirty-six to forty hours *in utero*.

Dr. Kraus professes to have conducted his experiments very carefully, and to have repeated them with sufficient frequency to insure a high degree of certainty to his induction. I cannot profess to have observed with frequency as concerns the homologous functions in the female; for only one case in all my practice has ever offered the necessary opportunities for exact observation, and, on looking over the literature of the subject, I find no data to assist in forming a conclusion. For the present, then, so far as I know, our views of the relative functions of the ovaries and the womb in menstruation must rest on the testimony of a single series of studies.

The case was one of uterine inversion and consequent protrusion from the vagina; that is to say, the womb was completely turned, the body of the organ having descended through the cervix in such a manner that its internal surface was presented externally between the labia. I made repeated attempts to reinvert the organ, but the work was one of slow degrees, and had to be continued at intervals during four successive menstruations, as after each operation a lapse of some days was required to repair the damage from laceration, by pressure and other means employed to correct the displacement. Having prepared to operate one morning, with the hope of finally disposing of the problem, I observed, on exposure to the light, a deep red blush suffusing the whole surface presented to inspection, which consisted of course of the lining membrane of the organ. On making the necessary inquiries, and consulting my notes of the case, I found that the patient was within four days of the menstrual period; for during the treatment her catamenia had been regular, and the calculation could be readily and accurately made. I consequently desisted from operating, and observed the progress of the infra-uterine blush from day to day. It continued to thicken until it was about four lines deep, and had the appearance of a flattened mass of currant jelly retained in place by the decidua. Closer scrutiny revealed the fact that the mass was, in the main, an undoubted product of the utricular glands, and hence a true uterine secretion.

On the fourth day after the appearance of the uterine blush the jelly commenced to break up, and a thin, scanty, pink fluid began to escape from the orifices of both fallopian tubes. The proper menstrual discharge now commenced, consisting of course of the disintegrated uterine blush, commingled with the pink fluid oozing from the fallopian canals. The latter did not constitute more than a hundredth part of the whole discharge. I had, during the progress of the case, four opportunities for observing the process, and in neither instance was there any material variation from the details I have described, either as respects the precession by four days of the uterine blush, or as respects the relative quantities of fluid generated *in utero* and discharged from the ovarian aqueducts. Actual volumetry was impracticable under the circumstances, and I only express a judgment from ocular data when I state the ovarian to the uterine product as 1 to 100. What special part the infra-uterine secretion plays in, or in what manner it promotes, the phenomenon of fertilization, must remain as yet an undecided question; but when it is considered that the prostate gland in the male is the proper homologue of the womb in the female, the inference is, I think, a fair one that the uterine secretion acts as a menstruum, protecting the ovum, and that its absence would be followed by infertility. In the egg-laying animals, without exception, so far as I know, the oviduct supplies the menstruum, which is secreted by special series of glands near the junction of the tubes. In the rodentia, as I am informed by a gentleman who has made a careful study of their development, the womb is cleft longitudinally by a well-marked fissure during the youth of the animal, and commences as an enlargement of the tubes at their junction and a little above; while in the higher vertebrates, even at maturity, there is considerable variation as concerns the distinctness with which its bilateral structure is marked. The most important aspect of these observations, particularly to the practitioner, is, however, that they may serve as the basis of an intelligible theory of the various pathological states with which the gynæcologist has to deal. As a matter of fact, my observation has been that most forms of uterine displacement have their starting-point in catarrh. How catarrh has its origin, and its importance as a derangement of function, are things readily appreciated with a correct conception in mind of the fundamental importance of the glandular structure concerned in normal menstruation. Hyperæmia ensues, the uterine tissues become loaded and engorged with blood, the organ is distended and enlarged, and some form of displacement follows as a natural consequence. Anteversion is, I apprehend, rather the most common aspect of the lesion. Now, one of the necessary accompaniments of hyperæmia is distention of the arterial feeders of the hyperæmic organ, with more or less contraction or obstruction of the venous system, by pressure partly, and partly, I am inclined to think, by an original act of nature resulting from the tonic influence of irritated nerves on the coats of the venous vessels. The anteversion, by doubling the venous tubes upon themselves, still more materially obstructs the circulation, and so perpetuates the inflamed state. Ulceration, as one form of resolving inflammation, usually follows, if the patient is a healthy one. If not, the exudation, in place of being resolved in this manner, may take the form of a tumor, cancerous, or less malignant, depending on constitutional bias. It cannot be too firmly held in mind by practitioners that obstruction of the venous circulation, however slight, is, if long continued, always fraught with peculiar danger to the tissue in which it occurs; since the various products of decomposition that are ordinarily disposed of by oxidation become accumulated as local *materies morbi*, and must necessarily give a more or less malignant type to the product of the exudation.

It follows, then, as a matter of course, that the restoration of the venous circulation to its normal function is a condition precedent to the healthy resolution of the hyperæmia, or of any pathological product in which the consequent exudation may have resulted, either by suppuration or by absorption. In anteversion, incision peculiarly favors this essential condition, by straightening the flexed vessels, and by temporarily relieving the arterial pressure. The *rationale* of the operation

seems to me to be so simple and conclusive of its value, that I am inclined to recommend it, in cases of no very great severity, as about the only means of effectual and permanent cure. A slight hemorrhage, even, provided it has its origin in venesection, may be of great benefit to the engorged tissues.

115 East Thirtieth street, New York.

Progress of Medical Science.

On the Displacement of the Uterus by Distention of the Bladder.—Dr. Braxton Hicks recently read a paper on this subject before the *Obstetrical Society* of London, detailing the results of numerous experiments he had made on the dead body, in conjunction with Dr. Goodhart, of Guy's Hospital. The following are the conclusions he drew:

1. Distention of the bladder takes place first backwards towards the sacrum and then upwards. As a general rule, the uterus becomes retroverted when moderate distention has taken place, often so much so that it becomes horizontal. Further distention, though generally completing the retroversion, may distend the anterior wall of the vagina, and so tend to remedy the retroversion, but encourage flexion, more especially if the cervical attachments be firm.

2. If the rectum be full when the bladder is distended the uterus does not become retroverted, but is raised bodily in the pelvis in an axis more or less perpendicular to the plane of the brim.

3. If the vaginal portion of the bladder be relaxed, the vagina first becomes distended and the cervix uteri is carried backward. The uterus is then carried backwards and rendered vertical; at first it is somewhat anteverted, but ultimately raised out of the pelvis in a nearly upright position.

4. If the uterus is at first retroverted and the vaginal portion of the bladder is first distended, the retroversion is restored.

Dr. Williams, in some similar experiments made in 1873, found that the uterus became *anteverted* when the rectum as well as the bladder was distended. Dr. Hicks thought that this was due to the distention of the rectum being artificial and producing an elastic pressure such as never could arise from a collection of fæcal matter.—*The Obstetrical Journal*, August, 1876.

Poisonous Properties of Glycerine.—M. Dujardin Beaumetz, having noticed the tendency to employ glycerine internally, in the treatment of diabetes for instance, and believing that it ought to be reserved for external use, was induced to investigate its effects on the economy when administered in large doses. Berthelot has shown that this substance is a triatomic alcohol, and it should consequently produce effects identical with those of alcohol. The following are the conclusions he has derived from his experiments:

1. When chemically pure glycerine is introduced under the skin of a dog in quantities of from 2 to 4½ drachms for every 2¼ pounds of the weight of the body, it causes death within twenty-four hours.

2. The symptoms of acute glycerism resemble, within certain limits, those of acute alcoholism.

3. The necroscopic lesions of acute glycerism are analogous to those of alcoholism, which leads to the supposition that the toxic actions of the two substances are very nearly the same.

4. From a therapeutic standpoint, the introduction of large quantities of glycerine into the body is not devoid of danger.

It is necessary, then, to use care in prescribing glycerine for internal use, and not to lose sight of the fact, that, like alcohol, glycerine will prove a successful or an unsuccessful remedy according to its dose and mode of administration.—*La France Médicale*, August 2, 1876.

Pregnancy and Traumatism.—The Record recently published an abstract of M. Guéniot's interesting paper on the "Influence of Traumatism on Pregnancy;" in a more recent paper M. Guéniot considers the influence of pregnancy on traumatism. The following are his conclusions:

I. As a rule, pregnancy exerts no unfavorable influence on the traumatism. Contusions and wounds, luxations and fractures do not present a larger percentage of mortality in pregnant women than in other classes of humanity; healing takes place according to the manner and within the limits of time proper for each variety of injury.

II. To this rule the following exceptions must be noted:

1. When the traumatism implicates the genital zone, its course may be retarded or complicated, or its termination aggravated by the condition of pregnancy.

2. The same must be said of injuries of the lower limbs, or of any region that may be the seat of vascular alteration, after the third month of pregnancy.

The complications to be guarded against in these cases, are: hemorrhage, angioleucitis, erysipelas, gangrene, and ulcerative atony.

3. Although cases of ununited fracture during pregnancy are exceptional, this condition certainly does seem to some extent to retard the formation or the solidification of the callus.

4 In cases of complicated pregnancy (especially when the complication predisposes to premature delivery), traumatisms, by exciting miscarriages, acquire indirectly an altogether exceptional gravity, for the woman is then exposed to the various dangers of parturition (hemorrhage, metro-peritonitis, uterine phlebitis, &c.).

III. The post-parturient state does not interfere with the regular cicatrization of wounds or consolidation of fractures, provided the lesions were contemporary with the pregnancy or the parturition. The exceptions to this rule must be attributed to an implication of the genital zone, or to the existence of milk fever, or to a general or local morbid predisposition on the part of the patient.

On the other hand, injuries received during the post-puerperal period seem to possess a peculiar gravity. Hence the necessity for deferring non-urgent operations on the genital zone or lower limbs for some three or four months after confinement.

IV One of the modifications engendered by pregnancy consists in a quantitative plethora, and as a consequence the globular hematosis is restricted to a degree that exalts the plastic force necessary for the reparation of wounds. It is to this sarcogenic property that the rapid increase of some malignant tumors during pregnancy must be attributed.

V. Finally, it follows from the above, that surgical operations during pregnancy are not as dangerous as they are generally supposed to be, and that in case of a rapidly growing, malignant tumor, extirpation or amputation, and not premature delivery, should be resorted to.—*Le Mouvement Médical*, July 8th.

The Influence of Purgatives and of Inanition on the Proportion of the Red Globules of the Blood.—At the meeting of the *Société Médicale des Hôpitaux*, on July 14, M. Brôuardel read an interesting

paper on this subject, of which the following is a *resumé*. A marked concentration of the blood follows the use of a purgative that occasions from one to four evacuations. Within the first twenty-four hours there is an augmentation of from 200,000 to 1,000,000 in the number of red globules contained in a cubic millimetre of blood. This augmentation may even precede the first alvine evacuations. After twenty-four hours the proportion of globules returns to what it was before the administration of the purgative. The white globules are sometimes increased, sometimes diminished in number, apparently following no fixed rule. The immediate effects of purgation then, is to concentrate the blood by depriving it of its serum ; but this effect is not lasting. It is necessary to bear this effect in mind when considering the curves in the variations of the globules in the course of disease

Inanition produces to some extent the same effects. M. Lépine has proved that during the first days of life the infant lives on the serum of its blood, and the number of globules in a given volume of blood is consequently increased; after a few days it begins to nourish itself with milk, the serum is reproduced, the globules neither increasing nor diminishing in number, and the proportion between the globules and the serum is changed. The same process is met with in the adult. M. Brôuardel had under treatment a man, 48 years of age, who by mistake had swallowed a mouthful of sulphuric acid. The patient vomited immediately everything he ate or drank, though there was no stricture of the œsophagus. At the end of four months he died, actually of inanition. The autopsy revealed a cicatricial stricture of the pylorus, which would hardly admit a probe. Two days before death the numeration of the globules had given the following results: red globules, 4,849,395; white globules, 7,852. The blood was so concentrated by the loss of its serum that it was viscid and as thick as syrup. It follows, then, that to make a man plethoric it is sufficient to purge and diet him.—*Gazette Hebdom. de Méd. et de Chir.*, August 4th.

Colles' Fracture and Dr. Carr's Splint.—Dr. H. Martin says that he has in six years treated about forty-five cases of fracture of the lower two inches of the radius with Dr. Carr's splint, and that in none of these could any deformity be recognized at the time the apparatus was removed. Many of these cases were seen years after the injury, and in not one was he able to detect, by any deformity, which arm had been injured. Dr. Carr, a physician practising in New Hampshire, invented his splint in 1843. It consists of a strip of light wood, one-sixth of an inch thick, eleven and one-half inches long, and two inches wide, on which is laid a carved wooden bed, the irregularly convex surface of which is exactly adapted to the concavity of the anterior surface of the radius. An oblique cross piece, round, four inches long, and one inch in diameter, is attached to its distal end. The inventor's idea was that, the radius being a much curved bone, treatment of its fractures on a perfectly flat splint could only result in more or less deformity of the bone itself and in such a change in the relations of its lower articulating surfaces as must necessarily induce more or less impairment of the symmetry and usefulness of the wrist. In a splint recently invented by Prof. Gordon, of Dublin, the concavity of the radius is recognized as an indication for treatment, but the convex bed is applied to the *side* of the bone, and not *under* it. In preparing the splint for use, four thicknesses of cotton sheeting are laid on its upper surface, and the lower surface of the forearm is then laid on this and secured by a few turns of bandage. If the patient now grasp the cross bar as strongly as possible, the action of the hand itself will, in a large proportion of cases, reduce the fracture; a light splint, eight or nine inches long and two inches wide, is then applied to the back of the arm as low down as the metacarpal junction, and a bandage applied from the middle of the metacarpus to the proximal end of the splint. Of course the fracture may, if desired, be reduced before applying the palmar splint. After a week the bandage need not extend below the carpus; but this joint should then be firmly bound to the palmar splint by a strip of plaster. The cross bar keeps the hand inclined to the ulnar side, while at the same time the patient has free use of the fingers, and later of the entire hand. It is not necessary to remove the bandage at all during the course of treatment, except it may be necessary to tighten it. When properly applied, the pain is entirely relieved very soon after the arm is "put up." The great advantages of this splint are that it relieves the patient of much discomfort and disability and leaves the hand ready for use and free from stiffness when the fracture is sufficiently consolidated for its removal. It is also admirably adapted to secure perfect rest of the joint in cases of sprains of the wrist.—*Boston Med. and Surg. Journal*, August 17th.

Rabies successfully treated by Woorara.—The *Veterinary Journal* for July states that Offenberg, in his recent inaugural dissertation at the Berlin Hospital, reported the case of a girl, twenty-four years of age, who was taken with the symptoms of rabies eighty days after being bitten by a dog supposed to be rabid. Injections of morphine and inhalations of chloroform having been used without benefit, seven injections of woorara, amounting in all to three grains, were given in the course of five and a half hours. First, the muscles became steadier, and the convulsive seizures less frequent, then the dread of water and the photophobia disappeared, and the voice improved. Some symptoms of paralysis now appeared, which reached their maximum the next day. On the second day there was a slight relapse of the symptoms of rabies, which was checked by an injection of a little less than half a grain of the woorara. The patient recovered slowly; a certain degree of weakness and sluggishness, and especially weakness of sight, remaining at the end of two months. There was inflammation, but no suppuration, at the points of injection.—*Medical Press and Circular*, July 12th.

Syphilitic Infection of the Mother through the Child.—A short time ago, M. Diday, of Lyons, read a paper on this subject, in which he maintained the following point: syphilis may be transmitted from the father to the mother through the agency of the child. In the cases adduced by M. Diday in support of this theory, the disease was first manifested in the mother by the occurrence of secondary symptoms, no initial chancre having existed. The child begotten by a syphilitic father, without actual lesions, may infect the mother at any period of its intra-uterine life; either when it is in the condition of an ovule, or of an embryo, or of a fœtus. M. Diday admits the rarity of syphilitic infection by conception. The immunity is frequent, perhaps, because of an anterior syphilis, either evident or concealed, but often, probably, because the morbid influence is of a feeble nature. The morbid impression which the mother has sustained enables her, in these latter cases, to nurse her child without danger of infection, while, on the contrary, a strange nurse would be in great danger. M. Diday will continue his researches, and hopes to be able to present a complete solution of the question at the next session of the Society.—*Gazette Hebdom. de Méd. et de Chir.*, September 1st.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 21, 1876.

THE FEVER OF THE CENTENNIAL EXPOSITION.

So many people who have visited the Centennial grounds during the past few weeks have been affected with a low grade of fever and diarrhœa, that there does not seem to be much difficulty in associating the two circumstances in the relation of cause and effect. Upon what this disease depends is still an open question. Those gentlemen who have attended cases in this city are inclined to believe that the water supply at the Centennial is tainted by sewage. They maintain that it bears a striking resemblance to those cases which occurred many years ago in the Willard Hotel, at Washington, and more recently at the Lake Mahopac Hotel; in fact, that the fever is just such an one as would be caused by contaminated drinking water. If this can only be proven we have a clear case at once, and are ready to call the commission having the sanitary affairs of the grounds in charge to account. Taking the *post facto* line of argument, we certainly have a right to presume that something is wrong with the sewage, either in the grounds themselves or in their immediate surroundings. A distinguished medical gentleman of this city has allowed such a presumption to take so much the force of a conviction, that he has given the homely yet appropriate title of "cesspool" to the class of fevers to which he says the one in question belongs.

It does not behoove us to jump at conclusions before we are in possession of some of the facts upon which they may be based. We naturally hesitate to believe that any commission having charge of the drainage of the grounds should so far neglect their responsibilities as not to take every precaution against soil contamination and polluted drinking water. This is, indeed, so strong an argument against the general theory of faulty sewerage, that in the present absence of facts we are inclined to seek for other explanations; at least we are exercising ordinary charity in giving any other probable causes, for at least the majority of the cases of so-called "Centennial Fever," serious consideration. We must take into account, in the first place, that fevers are apt to prevail during the autumn months, particularly after an extraordinary dry summer. Why this is so is in some degree explained by the long exposure of the beds of partially or wholly dried streams to the long-continued action of the sun, and the subsequent washing of contaminated watersheds by the heavy rains. Since it is the fashion to look to the character of the drinking water as one of the principal sources of fevers, it is at least fair to estimate these telluric conditions as of some account.

Again, sight-seeing is a very serious business by itself. One of its principal effects is a rapid and marked prostration of the nervous energies. The stranger from the country who goes to Philadelphia keeps his mind continually upon the strain, either to understand everything he sees, or yields himself to the excitement of continual admiration. The result is sometimes quite astonishing. The sturdy farmer who, when at home, can follow his plough from sunrise until bedtime, becomes exhausted after a few hours' stay at the Fair. He is, for obvious reasons, more apt to suffer in this respect than the blasé metropolitan, who is hardly astonished at anything, and who is inclined to take things easy. Add to this the tire of long journeys from home, insufficient rest, indifferent and irregular meals, the constant drinking of water, or, worse still, of the insipid and sloppy beverages which attract the more curious appetites, we have a reasonable explanation for many cases of diarrhœa, with attendant fever.

Some physicians who have visited the grounds, and who have enjoyed the means of observation, are inclined to explain all the cases of sickness on this account, while others as positively assert that the great majority, if not all the cases of fever are of a typhoid type, and are unquestionably due to the usual causes of that condition. This latter view is certainly quite well sustained by the persistency of the diarrhœa, its intractibility to treatment, and the alarmingly high average of mortality. At all events, it is wise, in view of the public anxiety, to use the greatest discretion in advising our friends and patients who intend to visit Philadelphia.

If we are not yet prepared to state positively that the main source of danger is in the water, we can at least err on the safe side by advising as little use of it as possible, except after having been boiled, or taken as in tea or coffee. Some physicians, in fact, have gone so far as to recommend the people to carry drinking water from their homes as a part of their necessary baggage. This is certainly sound practice, and will commend itself to the good judgment of all who wish to use every means of prevention which is in their power.

Referring to our belief that the subject of actual

causation of this peculiar fever and diarrhœa is still *sub judice*, we take occasion to say that we have sent a commission to Philadelphia to make a thorough sanitary survey of the Centennial grounds, to examine its source of water supply, the character of the drainage, and to study the fever as to its type, particular symptoms, and lesions. In our next issue we hope to present our readers with the results of such investigations.

Reports of Societies.

INTERNATIONAL MEDICAL CONGRESS.

SECTION OF OTOLOGY.

The Section met Monday afternoon, September 4th, at two o'clock. Dr. Laurence Turnbull, of Philadelphia, Chairman, and Dr. Charles H. Burnett, of Philadelphia, Secretary, as an act of courtesy to the visiting members, resigned their positions in favor of Drs. C. J. Blake, of Boston, and H. N. Spencer, of St. Louis. Dr. Blake returned his thanks for the honor.

EARLY TREATMENT OF AURAL DISEASES.

Dr. Albert H. Buck, of New York, Reporter, read a paper on the subject of the Treatment of Aural Diseases in their early stages, especially when arising from the exanthemata. His remarks were based exclusively on affections of the middle ear associated with the formation of pus. He stated that chronic purulent inflammation of the middle ear is a common affection among the individuals of a community; that the serious nature of this form of disease oftentimes impairs the hearing very markedly, and occasionally terminates in death. Hence, the great importance of preventing an inflammation of the middle ear from becoming chronic—for every chronic case (the tubercular, perhaps, excepted) must have originated in an acute inflammation. The anatomical relations of the middle ear afford an explanation of the serious results that may follow an acute inflammation of these parts, and also indicate what is the most important point to secure in treatment, namely, the relief of tension and pressure. This being the one thing needed, the writer called attention to the impotent nature of the means commonly employed for the relief of such an inflammation. He then referred to the great value of paracentesis of the membrana tympani as a preventive of chronic purulent inflammation of the middle ear, and all its serious consequences. Statistics from his own experience were given to show the value of this operation. The general practitioner was urged to acquaint himself with the use of the speculum and mirror, as means of ascertaining accurately the condition of the ear.

In the discussion that ensued on the subject of chronic discharges after scarlatina, Dr. Burnett asked whether there was anything specific that would cause so much chronic disease, or whether it was the result of neglect. There was nothing morbid that was necessarily productive of it, but the main disease being in the throat in scarlatina, the ear was neglected; the child being very young, no examination would probably be made. Dr. Buck's paper was addressed to general practitioners rather than to aurists.

TESTS FOR HEARING.

On Tuesday afternoon, Dr. Burnett, Reporter, read a paper on "The Best Means of Testing the Hearing," embracing a consideration of the character of the three principal tests (the watch, the tuning-fork, and speech) in use among aurists; deficiencies and discrepancies in the hearing power of the diseased ear, with the inquiry whether disease can be diagnosed by the manner in which an ear hears certain tests; and the manner of testing, including the importance of isolation of the better ear, during the test, in one-sided deafness, and a consideration of what is needed for any form of test, with conclusions favorable to the human voice as a means of diagnosis. These last were adopted by the Section after full discussion.

ARTIFICIAL DRUM-MEMBRANES.

On Wednesday, Dr. H. N. Spencer, Reporter, read a paper on "In What Percentage of Cases do Drum-Membranes Prove of Practical Advantage?" After reviewing the history of the artificial drum-membrane, he considered the condition of the ear admitting of its use; contra-indicating conditions; the forms of artificial drum-membranes (under which head a preference was stated for Yearsley's cotton-wool); and the offices performed, functional and therapeutical. When the conditions are the most favorable, it was claimed that the cases are the fewest in number where the artificial drum-membrane will be worn, whether the reasons be objective or subjective.

The conclusions of the Reporter, adopted by the Section, after considering the various forms of artificial drum-membrane in use, were that the cotton pellet is preferable for its greater simplicity and easier introduction, and the greater uniformity of its effect, and comparative safety in its employment; and that it possesses the advantage that it is a valuable means of treating the tympanum, a great future being in store for it as a therapeutic agent. It was also urged that the continued use of an artificial drum-membrane for improvement of the hearing is indicated in rare conditions which can only be determined by the aural surgeon. In the full and interesting discussion that ensued, the view was advanced by Dr. Burnett that improvement might be due in these cases to a certain amount of traction rather than of pressure on the malleus and chain of ossicles. Dr. Turnbull held the view that all foreign bodies within the tympanum were likely to induce increased irritability and inflammation. He could not understand how a piece of cotton could be attached to the inner edge of the perforation so as to make an inward traction.

THE HEARING OF SCHOOL-CHILDREN.

On Thursday, Dr. C. J. Blake, of Boston, Reporter, read a paper on "What is the best Mode of determining the Hearing of School-Children, and How should partially Deaf Children be Instructed?" He stated that the need for some provision in our public school system for the better instruction of partially deaf children is shown by the fact that while the number of cases of impairment of hearing in children is much larger than is generally supposed, the task of compensating for this defect is left entirely to the individual judgment of the teacher. From analysis of cases in children during school life, the writer made two general divisions of cases in which partial deafness is a symptom: those in which the hearing is so far impaired as to interfere with acquirement of articulation, and for which special instruction is absolutely necessary; and cases of partial deafness, from very slight impairment of hearing to the grave

defect included in the first division. For education of children under the first division the writer proposes the use of the system of visible speech successfully employed in the public school for education of deaf-mutes and semi-mutes in Boston. For children belonging to the second division, the advantages to be derived from association with hearing children, and disadvantages arising from creation of an additional department for instruction, are sufficiently great to favor instruction in mixed classes, compensatory advantages, however, being accorded to the partially deaf. To accomplish this it is necessary to determine the degree of deafness, by the establishment of simple rules for testing the hearing, examples and forms for which were given by the writer, to be used by teachers, or, better still, by competent professional examination, made by a medical supervisor of public schools; the creation of such an office, and its importance in relation to this subject as well as to general school hygiene, being strongly urged.

AURAL VERTIGO.

On Friday, Dr. Burnett read a paper on "Aural Vertigo with Variable Hearing," which created some discussion. The general opinion was that this form of vertigo might occur without permanent defect of hearing in those who were greatly fatigued or overworked, and that quinine diminished the amount of tinnitus aurium, instead of increasing it. The paper was based on a case accompanied with dizziness, nausea, vomiting, tinnitus, and variable hearing. It was argued that this differed from true labyrinthine disease, for then hearing was permanently lost, and that the case was probably caused by muscular spasm compressing the bones. Treated with bromide of potassium, followed by iron and quinine, the case got well. Several instances were mentioned by other gentlemen of true Mènière's disease, in which the good effects of sulphate of quinia and sulphate of cinchonia, even in severe forms of the disease, were marked, relieving all the other symptoms except deafness. One case was reported as having been seen in the wards of Prof. Charcot by Dr. Weir Mitchell in a recent visit; another in the practice of Dr. Turnbull.

CATARRH OF THE EAR.

A paper was also read by Dr. Samuel J. Jones, of Chicago, on "Modifications in the Treatment of Chronic Non-Suppurative Catarrh of the Middle Ear," in which the writer advocated the injection of slightly alkaline solutions or solutions of chlorate of potash into the Eustachian tube; and by Dr. Laurence Turnbull, of Philadelphia, on the "Proper Selection of Schools as well as the best Method of Instructing the Deaf and Dumb."

THE DEAF AND DUMB.

He alluded to Bell's method of visible speech as giving the pupil a knowledge of concealed parts of the mouth and throat used in articulating, and of the movements of each part, so that he is better able to gain conscious control over them. The method interests him in the practice of the elements and combinations, which gives him great power over his organs of speech, and obviates the necessity of informing him that a sound is wrong if it is not the one the teacher wishes to obtain. The symbolizing of odd sounds also leads the pupil to think and study about the parts of the mouth that produce them. If a child can hear sufficiently well to understand the teacher when near him, the ordinary school is decidedly better than a special school for him. Children sometimes become deaf after learning to talk and to read; these may profitably attend an ordinary school, provided the parents or teacher will take time to explain their lessons; if this is not done, the child often recites "parrot-like," without understanding what he has learned. This has been the experience of teachers of deaf-mutes, even when the pupil has learned to read the lips quite well. Congenital deaf mutes attending an ordinary school may learn to write, or rather to copy, and may perhaps get some ideas of numbers; but the teachers do not know how to reach their pupils' minds, even if they had the time to teach them. Advantage, however, is gained for deaf children in mingling as much as possible with those who hear.

After alluding to other points, Dr. Turnbull stated that if children are too deaf to profit by the instruction of the common school, and yet have had sufficient hearing to have through the ear acquired speech, instructors of the deaf are nearly or quite unanimous in the opinion that such should be taught by articulation and lip-reading, and the attempt should be made if possible to teach every deaf child in that way. Many of our congenital mutes speak so as to be understood by strangers, and will, we expect, make speech and lip-reading a successful means of communication throughout the world.

The paper was approved and referred to the Committee of Publication.

EFFECTS OF COLD WATER ON THE EAR.

Dr. Turnbull next introduced, as a practical subject for discussion, the effect of bathing, swimming, etc., as causes of aural disease. He considered these acts in cold water as an important and frequent cause of aural disease. Bathing in river or sea water is, when wisely and properly regulated, both healthful and pleasant. The result may be inflammation of the lower portion of the auditory canal and of the interior surface of the membrana tympani. The greater evil is sudden deglutition during diving or swimming while the mouth, nose, and pharynx are filled with cold water; the mouths of the Eustachian tubes open by the cold, and a portion of the water passes into the middle ear. This result is apt to occur in young beginners, but may also occur in old and experienced swimmers, owing to intense coldness of the water, while plunging head-foremost, the act of deglutition being entirely involuntary. Acute cases from swimming and diving occur during the summer months and chiefly in young boys, from eight to sixteen, a much smaller number occurring in the fall and winter. Unless the acute form is promptly treated, it is always followed by perforation of the membrana tympani, and discharge of shorter or longer duration. In cases not recognized, symptoms of violent headache, furious delirium, and coma create the impression that it is a cerebral disease, and it is so treated. In its first stage it is an acute inflammation of the mucous membrane of the middle ear, followed by effusion, and, after twenty-four hours, by pus. It is invariably attended by fever, with swelling and inflammation of the naso-pharyngeal space, and great pain. The indication is to remove this fluid or pus by an incision of the membrane, followed by the use of the air douche and hot water, and the ear is thus saved. The patient remains deaf for several weeks, and the local application of tincture of iodine, with or without some anodyne, around the back of the auricle, facilitates removal of the thickening. To diminish the discharge of pus, should it continue, employ powder of salicylic acid and starch blown into the meatus, and after a time washed out and dried, and reapplied twice a day.

The subject was discussed by every member present, and the conclusions were mainly adopted by the Section that the bad effects are brought about by sudden inhalations of cold water into the middle ear.

The Section then adjourned *sine die*.

Correspondence.

IODINE INJECTIONS OF THE HYPERTROPHIED PROSTATE.

To the Editor of The Medical Record.

Vienna, *Sept.* 20, 1876.

Sir:—The reported success of Heine of Prague, backed up by his six published cases of alleged cure of hypertrophied prostate, seems alike so brilliant and so encouraging, many a surgeon has doubtless waited with some impatience for fitting opportunities to show his triumph.

It may be scarcely necessary to state that the method of treatment recommended by Heine consists in the use of iodine, not simply in the manner so long ago proposed, but by injections into the body of the hypertrophied prostate. Heine claims for this treatment: 1st, that it does not cause suppuration nor undue irritation; 2d, that it induces diminution of the hypertrophy, and of course the bladder trouble consequent upon it. The little operation proposed for the cure of this grave disorder is so simple, the success to be anticipated seems so probable and so complete, that I think it important to show that in the hands of others than the author of the method, the results may be less brilliant, that in the most accomplished hands, indeed, this treatment may cause undue irritation, suppuration, and death.

Prof. Dittel, of the general hospital here, whose experience in diseases of the urethra, and particularly of the prostate, is probably unsurpassed, has not been slow to try the method of Heine, and as the following case has been under my own daily observation during the greater part of its history, I have been perhaps the more impressed with its warning.

The patient entered Prof. Dittel's wards the 21st of last November, with simple hypertrophy of the prostate, was easily relieved by the catheter, and was otherwise in good condition. The case was thought to be a good one for the method in question. Accordingly the solution as recommended by Heine, containing pot. iod. ʒ ij., tinct. iodine ℥ ij., aqua dest. ʒ ij., was prepared, and four drops of it at two different times, and a few days apart, were injected into the body of the prostate. No irritation or reaction followed immediately; but before the time for the third injection, inflammatory symptoms showed themselves. Fluctuation was afterwards detected in the prostate and the abscess opened. The inflammation continued to increase and spread; peri prostatitis, peri-urethritis, and peri-urethritic abscess supervened; peri-proctitis bringing up the rear of this long, unpleasant train. On the 13th of January it became necessary to perform supra-pubic puncture of the bladder, which afforded not only temporary relief, but induced considerable general improvement, never enough, however, to allow the supra-pubic route to be dispensed with. The battle was fought with bravery and great patience by both surgeon and patient; there was certainly not another case in all the wards the management of which was so troublesome and tedious. The patient gradually sunk under his many complications, however, and on the 10th of July died.

On examining the prostate, I found the seat of two old abscesses corresponding to the points where the injections had been made. The other lesions were recorded as "suppurative prostatitis, peri-prostatitis, cystitis, pyelitis, and nephritis."

I am informed that in the other instances also in which Prof. Dittel has tried this method, abscesses had resulted. My friend, Prof. Dittel, certainly is more than satisfied not to try the method again, but to leave it to others with a different experience.

Having seen in the New York Medical Record (which, by the by, is distinguished for its regular appearance on the files here) an account of the success of this method, as well as its freedom from danger, it is not unlikely that some of its readers may be tempted to incur unwittingly risks almost as disastrous to themselves as to the patient. And while I do not presume to condemn the treatment upon the limited evidence in hand, I think it important to add, and that without delay, the facts as above given, which without comment serve exceeding well to illustrate the other side of the question and to teach a caution which cannot be too carefully observed.

Benjamin Howard, M.D.,
Late Prof. of Surgery Univ. Vermont.

HYPERMETROPIA AND CHOREA.—A REPLY TO DR. STEVENS.

To the Editor of The Medical Record.

It is almost unnecessary to say more than a few words in reply to Dr. Stevens, whose letter appeared in the Record, Sept. 30th. He has presented an altered extract from one of Anstie's lectures (London *Lancet*, May 10, 1873) to prove that I have not said "very much," as he is pleased to express it, in regard to the etiology of chorea. I do not claim to have said more than is sufficient to account for the causation of the disease, and to refute his own theory.

If the gentleman had not labored under want of penetration, and had read Anstie's lecture to its end, he would have found that "the distinguished author" has given enough of the etiology to prove that the cause advanced by the gentleman from Albany is not only trifling but improbable, when compared with the conditions which influence the development and course of the neurosis under consideration.

Dr. S., however, has made several statements so manifestly out of the way, and he has placed me in such a false position, that I feel constrained to answer him. He refers to my remarks before the Academy of Medicine.

Now, if he had carefully read the report in the Record, and compared it with what I really did say before that body, he would have seen how greatly at variance were these two statements. In the printed account of the meeting, I am made in one sentence to say that my "attention had been called to hypermetropia, *and other eye symptoms in chorea*," and I had "found them secondary," and in the next sentence I am quoted as having said "strabismus was a common associate of chorea, and *no other* eye troubles had I found in connection with my cases of that disease."

I did say I had found hypermetropia (merely as a coincidence)—I *had* found secondary eye symptoms, among them strabismus. The others were orbicular spasm, disturbance of accommodation, etc.; but as to strabismus, with due respect to the "incomparable," I think every general practitioner has seen it as a

transitory symptom of several brain diseases, a most common example being tubercular meningitis, and in these cases it is the result of muscular spasm, and not connected necessarily with any congenital error of refraction."

I am quite as well aware as Dr. Stevens that hypermetropia, myopia, and astigmatism are congenital defects, and would remind him that this is one of the strongest arguments against his hobby. If this theory is true, chorea would not only be very much more common than it now is, but we might expect to find it at all ages. The authority with which he so confidently assails me says most decidedly that it is "a malady of that period of life which lies between the second dentition and the age of eighteen or thereabouts;" and again, "on the whole we may clinically divide the choreas into two main groups, those of childhood and those of sexual life."

It seems hardly worth while to bring other facts forward to disprove his theory, but I may be pardoned for presenting to the profession several reasons why his position is untenable.

1. A very small number of men, women, and children are absolutely emmetropic. Out of those that are at this critical day considered hypermetropic, the great majority would show one-sixtieth or less of deviation from the normal standard, which is absolutely insufficient as a cause for the production of a general nervous disease.

2. Nearly all cases of chorea are complicated with or follow rheumatic or cardiac disease, sexual derangement, mental trouble, ascarides and many other exciting and predisposing causes, some of which I have already named.

3. Certain varieties are symptomatized by jumping, leaping, or mental aberration, and others are connected with organic disease of the brain, of different kinds.

4. Dr. Loring authorizes me to say that the great majority of hypermetropes go through life without any chorea whatever, and this too while suffering from well-marked symptoms of asthenopia, such as inability to read but for a few minutes, at times tension across the forehead, and headaches. Feeling that the opinion of competent specialists, *pro* or *con*, would more satisfactorily settle this matter, I have appealed to several of our most distinguished ophthalmologists, among them Drs. Loring, Roosa, and others. These gentlemen are of the decided opinion that very few hypermetropes are chronic, and beyond the ordinary nervous symptoms of asthenopia it is difficult to say that the refractive troubles have any importance as a cause.

Dr. Stevens' opodeldoc story, with its delicate and cutting sarcasm, is undeserved. I seriously desired information whether he had had opportunities to observe chorea after he had primarily made the diagnosis of hypermetropia. I felt sure he was able to gratify my desire for additional knowledge of this curious connection.

A medical man whose extensive practice and advantages for observation enable him to report "more than seventy" cases of chorea, seventy cases of epilepsy, one hundred cases of severe recurring headache, and "many other neuroses," not to omit fifty-four cases of "epileptic insane persons," the majority connected with like conditions, should certainly have a great many uncomplicated hypermetropic patients under constant observation, and abundant opportunity to witness the development of some of the "functional neuroses of all kinds," that are "beyond any and all other causes combined dependent upon anomalous refraction of the eyes.

As the matter now stands, Dr. Stevens' theory is antagonistic with the observations of Trousseau, West, Jaccoud, Hughlings Jackson, Broadbent, Russel, Hillier, Radcliffe, Anstie, Kirke, and very many others.

In concluding my correspondence with Dr. Stevens, I wish to make a statement which in time I intend to fully prove, viz., that if errors of refraction play *any* part at all in the causation of functional neuroses, it is certainly a very small one compared to other influences that are well known; and though cases may be brought forward that are myopic or hypermetropic, we must remember the large percentage of the entire community that are the possessors of errors of refraction, and therefore take for granted that some of these individuals must have nervous diseases as well as affections of other systems.

I now trust that reliable and well-known ophthalmologists will note down how often they meet with, and report these nervous cases in their practice.

ALLAN McL. HAMILTON, M.D.

123 EAST THIRTIETH STREET, Oct. 4.

MEDICAL CENTENNIAL AFFAIRS.

THE MEDICINAL PRODUCTS OF NORWAY, SWEDEN, ITALY, SOUTH AMERICA, SOUTH AFRICA, CHINA AND JAPAN.

FROM OUR SPECIAL CORRESPONDENT.

PHILADELPHIA, *October* 14, 1876.

ACROSS the central avenue of the main building, directly opposite Norway, Sweden, and Italy, we find exhibits from South America, South Africa, and China and Japan. The medical display is not, as a rule, extensive or inviting, presenting only occasional features of sufficient attraction to arrest our footsteps. From the Argentine Republic are exhibited, in long, horizontal cases, probably forty feet in extent, with about 900 small compartments, the medical herbs, etc., of that region. They are only numbered, not named, and to study their nomenclature and recognize their qualities the visitor must obtain a catalogue from the attendant. Having done so, we find that they have been sent from the provinces of Mendoza, San Luis, Buenos Ayres, etc. The list fills many pages, but our ardor in the pursuit of information concerning them is somewhat dampened by the paragraphic announcement that "the medicinal herbs and plants of this country being as yet unknown to the scientific world, it has not been possible to classify them." The common name is alone given, and some of the medicinal virtues are also detailed. The quillo-quillo, for instance, of a saponaceous nature, is used as a medicine and also for cleaning clothes—a rare combination of good qualities. The girasol is employed for strengthening the eyesight; the cina-cina, for baths instead of mustard; the pago-palo de la Cruz, as an active purgative, fifteen berries being a dose; the camolote for phthisis, the leaf being applied to the lungs; tola, a preservative against the nausea experienced at great elevations from lack of oxygen in the air; agua sanguinaria, for cleansing and purifying the blood, and for dissipating the effects of blows, providing there be no fracture, etc. And so runs the story through hundreds of drugs, some of them with euphonious names, as the coralillo, poratillo, cardo santo, and retamilla; others decidedly more cacophonic, as the matapulgo, hojas de guindo, tulesquiri, etc., most of them mentioned without any therapeutic action associated with them.

There is also a case containing a truss or two, a single artificial arm and a leg, and club-foot irons, exhibited by Lacour, of Buenos Ayres; and Dr. Newberry, an American dentist of the same city, displays some sets of artificial teeth. There is another case in the same department with jars and vials labelled with such medical titles as, Solucion depurativa anti-Sudhan; Balsamico del Misionero, suspiciously like Friar's Balsam in name, Jarabe de Quinia y Fierro, etc. Papel Reactivo contra acidos surely must be test paper; but why send this and the other preparations so far from home? Some volumes of the *Revista Medica Chirurgica* are on exhibition in another case; and in a large pile of miscellaneous pamphlets, devoted mainly to statistics of this region, we notice a little volume entitled "Nociones de Anatomia Fisiologia è Higiene Humana," by Dr. D. Juan Bialet y Masse, which has been accepted as a text-book by the Department of Schools in the Province of Buenos Ayres. The Argentine Republic occupies a large space in the catalogue with items under the head of Medicine and Surgery, but many of them are grouped collectively under one exhibit. Thus we have medicines for animals, for the relief of itch in sheep, cholera medicine, cedron de puna for affections of the lungs, spurge from which castor oil is extracted, etc. The medicinal herbs are sent by a dozen different contributors, and will doubtless find a resting-place, by and by, on the shelves of some college of pharmacy.

From Chili I notice pharmaceutical preparations from Valparaiso, and two large cases of dried leaves, herbs, nuts, etc., some of which are medicinal, by various exhibitors. In one case there is some Café Preparado, said to be a new invention, and if intended as a substitute for the miserable solution or mixture administered to thirsty boarders in some hotels and boarding-houses, under the name of coffee, might be a very desirable article. Some scattered numbers of the *Revista Medica de Chili* momentarily arrest the attention of the medical visitor.

In the rear of this exhibit is that of Peru, the chief attraction of which is the display of mummies. On a shelf are a few bottles of various degrees of pharmaceutical interest, the contents being selected specimens of rhatany, canella, cascarilla, coca, etc. The grains of coca are about the size of small oyster crackers. Strange to say, there is not in the whole exhibit from this country the minutest particle of Peruvian bark. Other parts of the world into which it has been transported for cultivation with good results offer excellent samples, but the country which gives it its popular name, and which has thus had an honor permanently reflected upon it, is barren, so far as its exhibition to Centennial visitors is concerned. Much more prominence might also be given to the jar of dried leaves labelled "coca," for thousands would stop to take a glance at it, if they knew its wondrous virtues, reference to which has already been made more than once in the columns of THE RECORD. It will be remembered that while one writer condemned the use of coca because its victims sometimes lay in the fields all night long, rain or shine, dreaming beautiful dreams, others contend that it gives wonderful buoyancy and strength, relieving fatigue, dissipating weariness, and supplementing partially the use of food.

The republic of the Orange Free State, on the northeast boundary of Cape Colony, sends an interesting collective government exhibit, but the only thing of medical importance is a specimen of the cream of tartar fruit of that locality, a small gourd containing seeds, around which is a powder, similar to the bitartrate of potassium, but whether it possesses the diuretic or cathartic virtues of the latter I am at a loss to say. It is about to undergo analytic examination, I hear.

The Chinese medical exhibit has been pushed into the Mineral Annex, as a late comer which failed of accommodation from want of space in the department allotted to it in the main building. Each case has upon it the name of the port of shipment. It is a curious study of human nature in its semi-civilized aspects, to scan the thirty-five pages devoted to medical subjects in the thick quarto catalogue of Chinese contributions to the Exposition. The medicines are 750 in number, and are chiefly arranged under glass in horizontal cases, and each one in the list is preceded by the Chinese hieroglyphics, the value of each medicine being appended. Some of them are old familiar acquaintances, such as rhubarb and opium, but the quaint and curious uses to which less familiar therapeutic agents are applied somewhat surprise or at least amuse us. We are carried back several centuries to the days when epidemics of old were treated with mixtures of precious stones, goat's brains, urine, etc., when we find in the Chinese medical armamentarium of the present day the heterogeneous compounds and unmeaning substances to be presently referred to. Dried lizards, valued at Canton at eleven cents a pair, are among the first articles of their materia medica that attract our notice. We quote from this interesting Oriental catalogue the following descriptions of other items.

The fruit of the bitter-seeded cardamom is supposed to increase knowledge (as the Chinese characters of its name signify) by strengthening the stomach, with which organ the Chinese connect a person's disposition and mental capacity. The under shell of the land tortoise, which is strengthening and stimulant, is taken in decoction by the old and weak. The lining membrane of a fowl's gizzard, peeled off and dried, is prescribed in dyspepsia, diarrhœa, spermatorrhœa, and urinary disorders; the male bird being used in preparing the drug for female patients, and *vice versa*. Caterpillars are employed as purgatives and antispasmodics. The root of the panax ginseng is considered by the Chinese a very powerful life-prolonging medicine; hence its enormous price, being valued at Amoy at $7,000 a catty! Dried toads are described as tonic and sudorific, but bring only two cents apiece. Moss and ginger are employed together externally in articular rheumatism, a thin slice of the latter being placed over the joint, and the moss, being laid over this, is burnt, producing inflammatory action in the skin. Maggots are prescribed in the delirium of fever and in dysentery. A delectable compound is made by mixing boy's urine (girl's, we presume, would be less efficacious), gypsum, and dew, and stirring with a piece of mulberry wood; the substance deposited being prescribed in phthisis, gonorrhœa, and spermatorrhœa, and being also used as salt with rice. A whole catty of it costs but twenty cents at Amoy. The curious inquirer may find all these and scores of equally odd and fanciful articles on exhibition in the cases by asking the attendant to point them out to him.

In the Japanese exhibit, we notice a microscope and slides from the store of Iwasiya Ichizaemon, "Chemical and Surgical Instruments Export Druggist, No. 18 Honchio Sanchiome, Tokei." Under a framed collection of postage and revenue stamps, which many a juvenile collector would give his last nickel for, are about a dozen painted silk diagrams representing various surgical and other affections, such as necrosis of the carpal bones, sarcoma of the antrum highmori,

lupus, etc.; the artist's name, Sigeaki Yamado, being in the corner of each. Some specimens in the chemical exhibit, which is not an attractive one, are labelled with intelligible names, as tartarus emeticus, but the Japanese hieroglyphics on others were rather more than I could conveniently manage to translate in the limited time I had at my disposal. I noticed here a bivalve speculum, and a few ordinary litters, but they had no special interest or history. It may be stated in this connection that a medical college was founded at Tokio in 1872, that it has five hundred pupils, the course of lectures being in German, and that the instruction is given both in a preparatory school and a college.

Passing next to Portugal, we find a collection and also an individual display of drugs, such as pills of Proto iodureto de Ferro Inalteravel, from Lisbon; Xarope Pectoral Calmante de Lauro-cerejo, etc. A number of manufacturers exhibit Aguas Alcalinogazosas and Agua Mineral. One of them, the Pedras Salgadas Mineral Water Company, states that it received the "prise" at Vienna, and that the waters have been examined and approved by the Society of Medical Sciences of Lisbon. The analysis given of these springs by "the celebrated professor of chemistry in the Polytechnic School of Lisbon, Dr. Joseph Julius Rodriguez," presents a formidable list of alkaline bicarbonates and salts in the waters from four different springs. The combination of therapeutic qualities which they represent may be briefly quoted as follows: "The action of these waters is incontestable for diseases in the organs of digestion; . . . indubitable in curing diseases of the skin; . . . they are already to be found in the rooms of many hair-dressers, who acknowledge their superiority over other means employed against scurf." Serzedello & Co. also display a "Grande Deposito de Drogaria e Productos Chimicos," consisting of acids, ethers, and essences.

In the Turkish department, Herm. A. Holstein, of Constantinople, makes a very beautiful display in a large and handsome case, of different varieties of gum tragacanth, some of it almost white, oil of sandalwood, opium from Asia Minor, scammony, nut-galls, anise, etc. Such a valuable and choice collection should, if possible, be retained in this country.

R. J. D.

KIRKWOOD (S. C.) AS A WINTER RESORT FOR INVALIDS.

To the Editor of The Medical Record.

New York, Sept. 26, 1876.

My Dear Sir:—At this season, when so many are making plans for spending the winter in a milder climate, I have thought that a few words on the subject of a "Southern Home" might be of service. I have never had personal experience of Colorado, Santa Barbara, or other of our Western homes for invalids, and would not therefore be understood as comparing relative merits; but I had opportunities last winter of becoming tolerably familiar with certain portions of the South, and would simply give the results of my observations and experience.

The member of my family for whose benefit I spent the greater portion of last winter away from New York has not absolute pulmonary disease, but is one of that class whose lungs, in common parlance, are "not strong," while I have no lungs that trouble me, but am, *O misericordia*, a victim of acute articular rheumatism. The elements of climate particularly necessary to the welfare of those suffering from pulmonary affections, are:

1. Freedom from moisture.
2. Freedom from sudden and excessive variations of temperature.
3. The presence of a certain terebinthine element in the air.

In addition to these qualities of climate, it is important that the patient have pleasant surroundings, and a diet abundant in quantity and variety, and, what is not always found at the South, well-cooked.

Camden, S. C.—or rather Kirkwood, about a mile from the town—is situated on some piny sand-hills, at an elevation of about 240 feet above tide-water. Owing to the peculiar nature of the soil all moisture is almost immediately absorbed, so that the air is remarkably dry. As regards temperature, while, as throughout the entire South, there are a few cold days, we find none of that extremely penetrating cold experienced in places nearer the seaboard, nor, on the other hand, do we have any of that excessively enervating heat met with in places farther south.

The pine trees and turpentine stills in the vicinity give the air a terebinthine odor, most soothing to those harassed by cough.

From a table of observations made during the early part of the present century by one of the most respected citizens, I have copied a few statistics, which, I think, give a fair idea of the present average temperature.

1810.

January.		February.	
7 A.M.	40.70°	7 A.M.	40.77°
12 M.	51.60°	12 M.	58.07°

March.

7 A.M.	45.38°
12 M.	60.75°

1815.

January.		February.	
7 A.M.	36.26°	7 A.M.	38.28°
9 P.M.	42.70°	9 P.M.	45.53°

Whether from the absence of furnace heat—our rooms were warmed by large, open wood-fires—or to the dryness of the air, my two children, neither of whom had ever before passed a winter free from croup, showed not a symptom of it, though exposed in all weathers, in fact almost "living out of doors," in rainy as well as pleasant weather.

One word in relation to the people there. During the war they suffered terribly, both in the loss of property and kindred, and now almost all are much reduced; yet I have never met with a more refined or cultivated society, nor have I ever been where I was more cordially received, or where more sincere sympathy was extended in times of sickness and anxiety.

Very truly yours,

Willard Parker, Jr.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from October 8th to October 14, 1876.

Randolph, J. F., Surgeon. Granted leave of absence for four months. S. O. 208, A. G. O., Oct. 6, '76.

McKee, J. C., Surgeon. Granted leave of absence for one month and twenty days, with permission to go beyond limits of this Division. S. O. 138, Div. of the Pacific, and Dept. of California, October 2, '76.

Hartsuff, A., Surgeon. Leave of absence extended one month. S. O. 110, Div. of the Missouri, Oct. 6, '76.

Reed, W., Asst. Surgeon. Granted leave of absence for one month, with permission to apply for an exten-

sion of fifteen days. S. O. 119, Dept. of Arizona, Sept, 27, '76.

Koerper, E. A., Asst. Surgeon. Assigned to duty at Camp Sheridan, Nebr. S. O. 137, Dept. of the Platte, Oct. 6, '76.

Wilson, Wm. J., Asst. Surgeon. Leave of absence extended four months on Surgeon's certificate of disability. S. O. 211, A. G. O., Oct. 10, '76.

Wood, M. W., Asst. Surgeon. Assigned to duty at Camp Robinson, Nebr. S. O. 137, C. S., Dept. of the Platte.

Appel, D. M., Asst. Surgeon. Assigned to duty at Fort Stanton, N. Mex. S. O. 206, Dept. of the Missouri, Oct. 4, '76.

Practising without a License.—In Judge Gildersleeve's court, John Lang, of 1012 King street, has been tried and convicted for practising medicine without a diploma or license from the County Medical Society. The defendant was arraigned under a statute passed May 11, 1874, declaring it to be a misdemeanor to practise medicine or surgery without license or diploma from some chartered school, State board of medical examiners, or medical society, etc. He was found guilty, and, through the leniency of the court, fined only $50. The defendant is a native of Germany, and sixty-four years of age.

Dr. Orsamus Smith died of acute phthisis, September 19th, at the age of forty years. He graduated at Bellevue Hospital Medical College, class of 1862, after which he entered the U. S. Army medical service, and was Assistant-Surgeon of the 10th Regiment, N. Y. Volunteers, until the regiment was mustered out, May, 1863; Surgeon of the 84th Regiment, N. Y. Volunteers, in 1864, and of the 5th Regi- N. Y. Volunteers, until the close of the war. Having a decided taste for military medicine, and gifted with more than ordinary executive ability, the U. S. Marine Hospital Service opened to him a field of usefulness, and invited the exercise of his best talents. He soon attached himself to this arm of the service, and at once became identified with every movement calculated to advance its interest and extend its usefulness. At the time of his death he was Surgeon in Charge of the U. S. Marine Hospital, at Mobile, Ala., a position which he filled with great satisfaction. Added to the quality of a thoroughly educated physician, he had that of a gentle and sympathizing nature, which made for him warm friends wherever his social or professional duties called him.

Prof. Axenfeld.—The death of Prof. Axenfeld is another very serious loss to the faculty of Paris. He was the successor of Andral in the Chair of Internal Pathology, and, though young, had already achieved a brilliant reputation as an instructor and writer. He is best known by his *Traité des Névroses*, which passed through numerous editions. For the past four years he had been confined to his bed by a painful and incurable malady.

The late Doctor F. C. Rau, of West Hoboken, N. J.—At the regular meeting of the District Medical Society for the county of Hudson, N. J., held on August 2d, his death was announced, and, through a committee appointed for the purpose, the following action was taken:

Whereas, It has pleased the Almighty God to remove from our midst our late fellow-member, Doctor Frederick C. Rau; therefore

Resolved, That in the death of Doctor Rau our profession has been deprived of an earnest and conscienscious member, and the public has lost the services of an able and faithful physician.

Resolved, That we tender to his family and friends our hearty sympathy.

Resolved, That a copy of these resolutions be sent to the Medical Record and to the Standing Committee of the Medical Society of New Jersey.

Committee { J. R. Waldmeyer, W. R. Fisher.

[We regret to say that the appearance of the above item has been delayed until this time, in consequence of pressure upon our columns.—G. F. S.]

The late Dr. D. Brainard Hunt.—At a special meeting of the Medical Staff of the Out-Door Department of Mount Sinai Hospital, held Oct. 2d, 1876, the following resolutions relating to the death of Dr. D. Brainard Hunt, late a member of the Staff, were unanimously adopted:

Whereas, Our late esteemed and lamented colleague, Dr. D. Brainard Hunt, has been unexpectedly removed from our midst; therefore be it

Resolved, That individually and as a body we express our deep grief at his sudden decease.

Resolved, That we look upon the death of our late friend, whose uniformly courteous, genial, and obliging demeanor caused him to be beloved by all who came in contact with him, and whose scientific attainments promised a bright future for their possessor, a loss to us personally and to society and the profession at large.

Resolved, That this Staff send to the bereaved relatives of Dr. Hunt their heartfelt sympathy in their affliction.

Resolved, That a copy of these resolutions be sent to the medical journals of this city for publication.

(Signed) Paul F. Mundé, M.D., *President.*
E. J. Messemer, M.D., *Secretary.*

At a meeting of the Medical Staff of the Northwestern Dispensary, held on Oct. 6th, the death of Dr. Hunt, late attending physician to the class for diseases of women, being announced, it was resolved that we, his associates, hereby express the deep sorrow occasioned by his loss. As a physician of unusual culture and attainments, and the possessor of all the qualities which mark the Christian gentleman, we shall ever cherish his memory.

To his family we tender the assurance of our sincerest sympathy in their bereavement.

In behalf of the Medical Staff,

R. J. McGay,
Geo. Henry Fox,
W. H. Katzenbach.

Original Lectures.

THE ANTISEPTIC METHOD OF DRESSING OPEN WOUNDS.

A CLINICAL LECTURE

By PROF. JOSEPH LISTER,

OF EDINBURGH.

Delivered at Charity Hospital, New York, October 10, 1876.

(Phonographically reported for THE MEDICAL RECORD, by Nelson W. Cady.)

GENTLEMEN:—It is a most unexpected privilege that I enjoy, of addressing a few words to you. Until just now, when I saw you all galloping with such speed from the steamer, I had no idea that I was to address so large a body of students.

You will, therefore, excuse me if the remarks which I may make should be extremely imperfect. If, however, as I understand my friend, Prof. Van Buren, you are already through him indoctrinated in the principles of antiseptic surgery, it is not, therefore, necessary for me to go much into details.

Well, then, as the patient is not quite ready, I will say a few words of introduction. The main principle of antiseptic surgery is to be illustrated in this case by opening a venereal abscess in the groin.

If we have a fracture, the skin being unbroken, everybody knows that such an injury is devoid of danger. We put on proper splints, keep the parts dressed, and there is no inflammation in the parts to speak of,—no constitutional disturbance and no trouble. But if it so happens that the skin is broken at the same time that the bone is broken, then we have an injury that used to be one of the most formidable in surgery. If we compare the two injuries, we see that the circumstance of this skin being broken is not, *per se*, of any material consequence at all; it may be that the simple fracture is much the more severe injury of the two. The bone may be comminuted, the vessels extensively lacerated, and a large amount of blood diffused. Whereas, in a compound fracture, we may have the bone simply snapped across, but the skin broken.

Now we know from other circumstances that the lesion in the skin does not in itself particularly constitute the injury; it is not the injury to the skin, *per se*, but the fact of the skin being broken. We all know that if a compound fracture is treated or not treated, in the course of three or four days we have an offensive discharge from the opening. I do not mean that a compound fracture not treated antiseptically will have such a result. It was known in the time of John Hunter that such a fracture, if covered over with cotton and air-tight dressings, and left alone, will go on as quietly as if the skin were unbroken. But suppose the skin is treated with poultices, you are sure to have a suppuration in two or three days. The blood within, the extravasated blood, putrefies. If any one were to talk of pouring a quantity of putrid blood into a recent wound, such a proposition would be received with horror; but everybody knows that pretty much the same thing takes place if the blood is allowed to putrefy in a wound. After a few days have elapsed, the wound becomes granulated, and as soon as granulation takes place, if the surfaces are brought together, there is apt to occur union by first intention.

It was shown by Pasteur, conclusively shown, it seemed to me, after reading his experiments, that putrefaction was a fermentation, that it was a manifestation of the existence of a ferment similar to that which exists in yeast.

When that was shown by Pasteur, then at once it occurred to me, here is a chance for improvement. We may possibly be able to prevent putrefaction in wounds if the cause of putrefaction in wounds is not the access of air, but of living organisms developed in the air, and which in the blood are the cause of putrefaction; then it may be that we may get hold of some agent which will be strong enough in its action upon this kind of organisms to destroy them without doing damage to the human tissues, just-in the same way as crab-lice are destroyed without injury to the skin. So in this case, if we can apply to our wounds some agent which may destroy the minute organisms, which are the cause of putrefaction, without injuring the wound, the problem is solved—it is no longer a question of hermetically sealing out the air; it is merely applying a dressing that shall act as a germ-destroyer to prevent the influence of these living organisms.

This, gentlemen, is our principle. The agent which we found in the majority of cases most efficient is carbolic acid. It had been used without my knowing it, in a medical ward in the hospital, and with great advantage, as an antiseptic. It had been used, as well as antiseptics of various kinds, for the purpose of *mitigating* putrefaction, not of *preventing* it; that is the great difference.

The principle of antiseptic treatment is to prevent the occurrence of putrefaction in the wound by the presence of the organism with which you have to deal. If you can prevent that, then your wound comes to be in the condition of a simple fracture.

Taking this example of a simple fracture, we feel as a matter of course that if we really can by any means adopt such a mode of dressing as shall be equally efficient with the unbroken skin, a wound, no matter how severe or contused it may be, and no matter what the patient's constitution, ought to be perfectly amenable to treatment.

You may ask, Why do you disregard the patient's constitution? My reply is, Do you regard the constitutional treatment important in a simple fracture in which we have a severe wound, contused, lacerated, and so on? If you could see such a case, you would say, Here is a wound that will not heal without sloughs and suppuration. Yet because we cannot see the injury, and because the skin is unbroken, we are apt to forget what is really the nature of the injury in a simple fracture, which I venture to say is as bad and much more severe than any that the surgeon ever inflicts. Yet no man regards the patient's condition in a simple case of fracture, but contents himself with the local treatment. If constitutional treatment is adopted at all, it is only in case of constitutional disturbance. . . . .

The treatment of an ordinary abscess, acute or chronic, under antiseptic management is, I think, one of the most beautiful points of the whole matter.

Suppose an abscess is opened in the ordinary way, that is, by a free incision. The result is, you get rid of your patient by opening his abscess; the previously maintained suppuration is gotten rid of by relieving the tension; but instead of the previously existing causes of irritation, you let in a new one, viz., the *putrefactive element*. The discharge remaining in the abscess putre-

fies, and, by reason of its irritating properties, ends in and keeps up the suppuration. But by this means [the antiseptic method] you prevent putrefaction, prevent the access of putrefactive elements, while at the same time you get rid of the tension by opening the abscess and introducing a drainage tube, while the so-called *pyogenic membrane* is left free of any disturbing cause at all, and as soon as the pyogenic membrane is free from disturbance it ceases to be pyogenic.

If you take the two flaps of a patient's thigh, where an operation has been performed by the double flap method, and lay the granulating surfaces together—taking away the dressings which our forefathers used to have between the flaps after an amputation, to make them lie apart—when you come to see the case next day, you will probably find a large extent of these granulating surfaces coalesced near to each other. Well, now, consider these surfaces one moment.

The granulating surfaces have no tendency to form pus unless they are irritated. Suppose that the granulating surfaces have a tendency to form pus, then if the two granulating surfaces are brought together we should have pus secreted. *Impossible.*

The secretion would still go on, although the surfaces were thus united and in contact with each other. There is nothing to prevent the possibility of the effusion of fluid, if it were the office of granulating surfaces to produce pus. The pressure would lead to tension and the formation of more pus. But even then there is no more serous effusion, that is to say, the serous effusion soon ceases after the granulations are brought together; for if the serous effusion still continued, the granulations could not coalesce. What is the fact? That leads to this remarkable result, that from that time forth the formation of pus ceases. It is simply disturbance that keeps it up, and nothing else; but when the granulations are put in contact with each other, they will protect each other perfectly from any irritating cause. The granulations of the previously suppurating wound thus protected, immediately cease to suppurate; very soon after they cease to form serous effusion, the tissues proceed to develop into the higher fibrous tissue of the cicatrix. There, gentlemen, you have evidence that the only thing granulations require is to be *left alone*, free from any serious disturbance, and the result will be that you will have no more pus. Open the abscess antiseptically; employ efficient antiseptic dressing, and at the same time provide for the escape of serous effusion, and the suppuration ceases from that time forward.

THE OPERATION.

The apparatus by which the carbolic spray is generated has been already described, so that it is not worth while to go into details. The few general principles which Prof. Lister laid down were of much importance, viz., that it was necessary, to the proper application of the antiseptic method, that the spray should be thrown out in large volume, extensive enough to envelop completely the hands of the operator, the instruments, and the site of the operation; and if at any time he was compelled to move his hand out of the spray, to take up a new instrument, he should dip his hands in the basin of carbolized water (aq. 20, acid carbol. 1) before using it, otherwise that neglect might be the means of introducing these minute organisms into the wound; that the skin over the point of operation should be very carefully shaved, so as to leave no parts unexposed to the action of the carbolized water which was to be applied to the integument for the destruction of any of these organisms which might exist upon it; that any neglect of the total destruction of all the organisms would be fatal to a properly considered antiseptic method of treatment.

The abscess in the patient's groin being opened in the usual manner at the most dependent point by a free incision, the Professor remarked that, as it was necessary to establish a drain, he was in the habit of using the india-rubber drainage tube of Chassaignac; that an important point in the application of this tube is that it should not be left projecting outside the wound, but should be flush with the surface; and that to keep the tube from being pushed into the wound, two small threads were fastened on either side of it; and that, as in the present instance, the tube was placed in an oblique position, it was necessary to cut the end of the tube in an oblique manner, so as to be made flush with the surface.

The abscess, when opened, discharged a large amount of grumous, offensive pus, which was carefully sponged away with carbolized water. Happening to pick up a sponge that had been dipped into the basin containing the chocolate-colored mixture of pus and carbolized water, he used it also, and remarked—in answer to some one who objected, that the sponge was foul with pus—that this was perfectly true, but that the sponge was *antiseptically clean*, and was, moreover, vastly cleaner for surgical purposes than the majority of sponges obtainable in the shops, because it had been dipped in the antiseptic fluid. Having emptied the abscess and put in the drainage tube, he applied the antiseptic dressing, which consisted, first, of several layers of carbolized gauze, to act as a compress; then of a larger layer, about sixteen inches square; next a piece of oiled silk, and finally of several more layers of gauze, the whole being confined to the limb with elastic bands, so as to keep out the air.

One of the windows of the amphitheatre happened to be open, and a current of air deflected the cloud of spray from the wound. Professor Lister at once called attention to this as an important point to be observed. The window must be shut, otherwise the spray would be diverted from the wound, allowing the access of the organisms against which the spray was intended to provide.

His minute attention to all such details made this lecture of unusual interest and importance.

Original Communications.

UPON CERTAIN NEUROSES FOLLOWING THE ZYMOTIC FEVERS.

By ALLAN McLANE HAMILTON, M.D.,

VISITING PHYSICIAN TO THE EPILEPTIC AND PARALYTIC HOSPITAL, NEW YORK, ETC.

CERTAIN eruptive fevers, particularly those of a serious nature, create in the nervous system a vast amount of mischief, and leave after-effects formidable in the extreme; because they defy treatment, and involve a structural change which is generally permanent.

In most of these acute disorders, when death occurs, the nervous system is the final *point d'attaque*, and coma, convulsions, and other terminations, constitute the last stages of the disease.

If these morbid conditions do not carry off the patient, he survives them to suffer some one of the neuroses it is my purpose to discuss. The exanthemata

which I shall allude to are variola and cerebro-spinal meningitis, although rarely scarlatina may leave behind it a great variety of nervous troubles—not only those dependent upon uræmic poisoning, but even degenerative diseases such as sclerosis or other structural alterations.

Various forms of local paralysis, occasionally hemiplegia, muscular contractions of a permanent nature, alterations in sensation, and affections of the organs of special sense, are morbid conditions that may sometimes follow either of the diseases I have mentioned. Convulsions, though more rare, are occasionally met with.

In one class of cases, those that have begun with varioloid, paralysis is sometimes left. The paralysis is generally due to changes in the anterior columns of the cord, and resembles very closely the other forms characterized by rapid wasting of special muscles or groups of muscles, as in essential spinal paralysis, and progressive muscular atrophy. Sensation is generally unimpaired, and there is decided bladder trouble and certain evidences (such as bed-sores) of a perverted state of the cutaneous nerves. In certain respects the paralysis, if it be paraplegic, resembles in many points the form due to myelitis.

As sequelæ of scarlet fever, we may have serious changes in the brain and cord, and permanent contractions. Tremors, or even many psychoses of an undefined character, may be sometimes met with.

Among the great number of cases that have survived cerebro-spinal meningitis, a certain number carry through life most terrible traces of the disease. Usually the pathological state is one of chronic meningitis located at the base of the brain and upper part of the cord. Gallup, one of the first medical men who wrote upon the subject, recognized these cases, and considered that the anterior and inferior parts of the brain were the localities which were the seat of the most violent inflammation. The involvement of certain nerve trunks, and the subsequent loss of function, particularly in the seventh and fifth nerves, enable us to satisfactorily define its site. Deafness as well as impairment of sight are striking and not uncommon results. Not unrarely the condition is connected with permanent contraction, or spasm of the post-cervical muscles, or by a decided pain running down the back and arms. A symptom I have often noticed with cerebral tumor is the dizziness which troubles the individual when he looks upwards. I have heard these patients complain of this trouble.

The appearance of facial neuralgia or sciatica (and these are not the peripheral varieties of the disease) is not uncommon in the adult who recovers from small-pox. A patient now under treatment, after a severe attack of variola which has left him deeply pitted, developed a most troublesome neuralgia of the fifth nerve two months after, and his condition after the subsidence of the fever, together with the absence of all other causes, pretty clearly proved the neuralgia to have been caused by the variola. Sciatica on the same side (the right), and a "heavy feeling" of the right side of the body, are other symptoms which rather point to some affection of one-half of the nervous system. He has continued three years in this state, and when I first saw him, two months ago, complained of the symptoms I have before alluded to. His right side was cold and slightly anæsthetic, and the muscles of the right leg somewhat atrophied. Excision of the supra-orbital branch of the fifth nerve, and all sorts of medical treatment, failed to relieve him. I am firmly convinced that his trouble originated in the cerebro-spinal axis.

Vulpian has related cases of neuroses following small-pox; and Janeway presented to the New York Society of Neurology, quite recently, a case of partial paralysis following close upon the heels of a severe attack of variola. The patient was a young man of about twenty who presented a paralysis of the extensors of the right arm and forearm. The biceps was entirely paralyzed, and there was no reaction to the faradic current, but contraction followed the galvanic.

The paralysis is confined entirely to the right side, the left hand being only slightly numb. Dr. Janeway was inclined to believe this condition to be the result of neuritis.

Other cases have been reported where the nervous symptoms were all provoked by a central disorganization of the nervous tissues. In certain cases decided changes, consisting of sclerosis or softening, were apparent after death. Westphall, Lockhart Clarke, besides Vulpian, have reported these cases. As I have said, they present certain homologous features.

Westphall's case was one of partial paralysis, which began in the feet and afterwards increased so that finally there was complete paralysis of the lower extremities. The patient was just able to move his great toe. Reflex movements were not provoked by any of the ordinary means. Paralysis of the bladder was present. Sensation was unimpaired.

His other case resembled this one in many points. Immediately after recovery the left leg was gradually paralyzed, and subsequently the right was affected. This patient had incontinence of urine and fæces. Suffered greatly with cystitis, and ultimately died. Both of these patients had bed-sores.

In Vulpian's case there was partial paralysis just as there was in Janeway's. This patient lived. He accounts for the affection of special muscles and the short duration by supposing the pathological condition to have been a temporary irritation at the roots of certain spinal nerves supplying the affected muscles. He considers the irritation to have resulted in the destruction of the cells in the anterior cornua, and atrophy or loss of function of the fibres of the anterior nerve roots as a consequence of the degeneration of the nerve cells with which they were connected.

Lockhart Clarke's case was caused by inoculation of small-pox virus. The patient was thirty-two years of age, and had been inoculated when he was one year old. Coincident with the eruption, the left arm lost its power and the right arm next followed suit. The muscles of arms, shoulder, and trunk atrophied and almost disappeared, and the heart's action was greatly changed, as it became irregular.

A few months before death he was carefully examined, and it was found that the muscles of arms and shoulders were scarcely developed. The muscles of the forearm had escaped the general wasting. The muscles of the ball of each thumb were very much wasted, while those of the fingers were unaffected. The lower extremities were perfectly normal.

Drs. Webber, Putnam, and Goss reported during the year 1873 several cases of paralysis occurring with variolous eruptions. Dr. Goss's case was one of varioloid. During convalescence there were deep pains (referred by the patient to the bones), which lasted for two days. They began in the left arm, and next day extended to the right arm, and both lower extremities were finally affected. The patient was unable to flex legs or thighs, and could not raise her head to her head. There was no paralysis of any of the muscles of the head, and her intellect remained clear. There was no abnormality of sensation except the

pain alluded to, which disappeared with the commencement of the paralysis. The patient died the next day.

Dr. J. J. Putnam's case was one of severe variola. The patient, a man, remained unconscious till the eighth day, and then complained of a weariness or heaviness of the right shoulder, which subsequently became the seat of pain. This symptom gradually disappeared, and Putnam was enabled to diagnose a paralysis of the posterior thoracic nerve. The lower half of the trapezius and the rhomboid muscles did not respond to electrical stimulus. Under strychnia the patient improved.

Besides the cases I have mentioned, Eulenburg and Pforzheim have collected a number; some of them presenting the symptoms of disseminated sclerosis. The others were paraplegiæ, and partial paralyses of different kinds. The latter recovered generally in a short time.

Even hemiplegia may be a result of variola; and the following case, in which epilepsy and hemiplegia dated from the small-pox, is perhaps a good one to illustrate the subject. The paralysis was due most probably to an epileptic seizure in which some vessel was ruptured.

M. J. T., 35 years, born in New York; no occupation; entered the Epileptic and Paralytic Hospital Feb. 11, 1870. Mother died of consumption; sister had epilepsy. First fits appeared at the age of five years; came on about three months after an attack of small-pox; hemiplegia of the right side came on same time, she believes, as the epilepsy. Before the fits she has cramps in the paralyzed arm and hand, and a feeling of dizziness; has it most frequently in the daytime, three or four at a time, once in three or four weeks. But shortly before her admission had them nearly every day. Circumference of skull, 20¾ inches; antero-posterior measurement, 13 inches; transverse, 13 inches; memory good, mind rather weak; speech good, sight good, hearing fair with left ear; cannot hear with right ear, even when the watch is pressed against it. Sensibility, pinching, and pricking appear entirely abolished on the right side from head to foot. Drags right leg in walking; has but little use of right arm and hand, the muscles of which have a tendency to spasmodic contraction; temperature somewhat diminished on right side; pulse, 96. Respiration apparently healthy, appetite fair, bowels rather costive. Menstruated at 13 years, and has been regular since.

Present condition, June 1, 1876:

Memory appears to be very good; the fits have decreased in severity and in number. Has but two attacks last month; none at night. Has hæmoptysis; has an aura of about a minute's duration; flexor of muscles of right hand are contracted; thumb is turned again, so that its inner part touches the under part of the index finger; lastly, the whole hand is somewhat drawn up, and lies in her lap with the palmar surface up. When directed to put hand up to shoulder it shakes right and left; this shaking is very violent, but only so when she moves it. It is, however, entirely quiet while in her lap. Has the irregular hemiplegia gait; protrudes her tongue straight; eyesight good, hears perfectly well. There is special paralysis on the side opposite the hemiplegia.

Cerebro-spinal meningitis leaves sequelæ much more interesting and obscure. Those cases that recover sometimes only escape with extensive changes in the meninges, and a form of low inflammation, confined usually to the upper part of the cerebro-spinal system. As I have said, the organs of special sense are affected in many cases, and the diagnosis from chronic basilar meningitis, which is progressive, can be made by bearing in mind the fact that the latter disease is progressive, and that affections of the organs of sense are from before backwards, while in the form of meningitis first alluded to the onset is sudden, dating from the attack, the anterior nerves being more often exempt. It differs from the ordinary meningitis in the fact that the symptoms of acute or subacute disease are expressed by very intense and rapidly fatal phenomena. This condition can be compared to the condition of the pleura after a severe pleurisy, in which disease adhesions, thickness, and other changes remain for years, rendering the patient liable to acute attacks at subsequent periods, and interfering with respiration. The patients I have seen have many symptoms alike, which are, I think, characteristic—a rigidity of the muscles of the upper part of the body—the head being held by the patient just as it sometimes is in what we familiarly call a "stiff neck." It sometimes necessitates a painful effort to turn it, for when such an action is performed a dart of pain runs down the shoulders and arms. A symptom, which I think is something more than hysterical, is the feeling experienced by the patient, who says there is a "cracking" when he turns his head. There is generally dull pain, sometimes localized, but more often diffused; much dizziness, occasional vomiting and mental uneasiness. It is rare for the disease to locate itself in the middle or lower part of the spine, for here the meninges are separated from the cord, and there is sufficient room for thickening without mechanical pressure; but occasionally the prolongations of the dura mater, which form sheaths for the spinal nerves, are the seat of such inflammatory action, and, as a consequence, darting pains, rigidity, and other symptoms are expressed.

Partial paralysis of one leg or arm is not an uncommon result, and even hemiplegia may follow. In one case that I remember, there was an attack of hemiplegia with total deafness. The child was unable to articulate, and remained in this condition for several years, not improving in the least. In another case—a girl aged 15—there was a rigid contraction of the flexors of the arm and forearm, and a contraction of the muscles of the back of the neck, which drew down the occiput to an uncomfortable degree.

In the spring of 1874 I saw the wife of a physician of northern New York, who had passed through a severe attack of cerebro-spinal meningitis two years before. After a slow recovery certain symptoms remained, which increased in severity up to the time of her visit. She was a delicate and slender woman, very nervous and hysterical, and easily worried. She manifested a train of symptoms very much like those I have already detailed—a feeling of constriction about the throat, a spastic, contracted condition of the post-cervical muscles, etc. When looking upwards she complained of dizziness, and constant dull headache; there were also pains over the spinous processes of the upper dorsal, and over all the cervical vertebræ. At times she heard noises and roaring, and suffered from otalgia. Convulsive jerkings of the head, and clonic spasms of the arms were occasional. Her pupils were normal, but the conjunctivæ were injected. Ophthalmoscopic examination gave negative results. "Crawling" sensations and coldness of hands were not uncommon.

Another case seen with Dr. Rankin, of New York, was of a most interesting and grave character. The child, previous to its acute illness—cerebro-spinal meningitis—was bright and attractive. After the disease had spent its force, she came out of it entirely changed.

Her mental condition was one of imbecility, and there were permanent contractions of the muscles of the upper and lower extremities. Deafness, with destruction of the tympani, and other life long infirmities, were left. Dr. Joseph Jones relates the case of a patient who had had cerebro-spinal meningitis in infancy, and recovered with complete paralysis of arms and legs, which were atrophied, "rigidity of spine," arrest of mental development, paralysis of tongue, etc., and he remained in a helpless condition for twenty years. The head and trunk were those of a man, but the lower extremities were withered and useless.

Gallup and other investigators dwell at some length upon the aural complications. The former repeatedly alludes to the intense energy of the inflammatory processes of that attack, not only the meninges in the locality, but also the tympani and the membranes which line the different cavities of the ear.

Dr. Samuel J. Jones, of Chicago, has reported several cases of auditory disease left in the wake of cerebro-spinal meningitis, and some of them present the grouping of symptoms I have here alluded to. In Case V. there was loss of speech, unsteadiness of gait, and other difficulties. The power of speech was subsequently regained. Case VI. was deaf and dumb. This case "curved his spine backwards," and his head was drawn in the same direction.

Occasionally a hyperæmic condition or actual meningitis will remain after typhoid fever. I have met with only one case of this kind. He was a patient of Dr. Wm. Shine, with whom I saw him. Two years ago he recovered from an attack of typhoid, and with convalescence he gradually lost power in the right hand, right leg, left leg and left hand in the order I have named them (this is his statement). Preceding these conditions there were shooting pains running down the spine and around the body. He was paraplegic two months afterwards. During this time reflex movements were easily provoked. "When my feet came in contact with the foot of the bed, if the cold wood touched them they would fly up." He evidently had the contractions which are so clearly symtomatic of meningitis. There was some constipation; no bladder trouble except atony. His neck "felt stiff;" there were also the pains I have before alluded to, and he was occasionally dizzy. The loss of power in legs has gradually returned.

Present Condition.—The patient walks fairly, with no apparent impediments. The skin is slightly hyperæsthetic; no atrophy of any muscles; has good muscular strength; there is slight tenderness produced by pressure over the vertebræ between the scapulæ; muscular contractions at back of neck, and some pain with movement; slight distention of abdomen by flatus (he says this is a constant symptom); bladder and bowels in excellent condition; some very trivial effort required to urinate; no headache, but dizziness caused by looking upwards; no loss of power in hands or arms; no constricting bands; patient can stand with eyes closed. Co-ordination of delicate muscular acts unimpaired; there are no twitchings at night left. I suggested the propriety of giving iodide of potassium in addition to the ergot Dr. Shine had prescribed. I also recommended the actual cautery.

In regard to the results of post-mortem examination I cannot do better than by referring to Fox. He details the autopsies of the cases of varioloid of Westphall and Clarke. Gross examination of the cords of Westphall's two cases revealed congestion of the gray matter, but the white matter and nerve roots appeared perfectly healthy to the naked eye; beneath the microscope, however, specimens hardened in bichromate of potash solution showed areas of softening in gray matter; certain parts were changed in color, and these altered portions were found to contain an abundance of fat granules. In Clarke's case the anterior cornua were the seat of decided changes, and in one locality a dilated vessel surrounded by a layer of exudation was found. The nerve cells in the anterior cornua were much reduced in size, and at some points had a granular appearance.

The appearance of the interior of the cranial cavity in the other disease hardly needs a description. The brains of individuals who have died of chronic insanity, furnish us with illustrations of what we may expect to find in chronic cerebro-spinal meningitis. Thickened, and pearl-colored meninges, blood-vessels with thickened walls, points of adhesion, and occasionally a compressed cortex cerebri, are natural results of the disease to be found at the base of brain; I have seen exudations and false membrane, atrophied nerve trunks, and adherent membranes.

It is almost unnecessary to add that the prognosis of these two varieties of disease is exceedingly bad. In one the structural alteration of the nervous substance is complete in most instances. In the other there is a disposition of the investing membranes of the brain, when once the seat of inflammatory action, to remain thickened. The vessels undergo obliteration, and the nervous tissue beneath is deprived of nourishment. In those parts of the cerebro-spinal axis where there is not room for increase in size, pressure upon the cortex must be the cause not only of inflammatory changes, but even of atrophy. Inflammation of the dura mater is rarely stationary; the more delicate membranes investing the brain invariably suffer, and as a consequence the small vessels which go therefrom through the cortex become occluded, and as certain parts are deprived of nourishment, minute foyér of softening must result.

As to treatment, very little can be done. I have great faith in iodide of potassium and belladonna. The actual cautery, not used superficially, but for the production of ulcers on the back of the neck and between the shoulders, sometimes relieves the patient, but at best the improvement will be of short duration in the majority of cases.

The New Hôtel Dieu.—Work on this new hospital is being pushed with great activity. The walls of the old Hôtel Dieu will be pulled down before the opening of the Exposition in 1878. The fountains for the hospital court are now in course of construction.

Progress of Medical Science.

On Filaria Sanguinis Hominis Ægyptiaca.—Dr. Sousino, of Egypt, has for some years had an Egyptian Jew, aged about fifteen, under observation for hematuria depending on bilharzia, and cachexia due to that and the presence of intestinal worms—ascaris lumbricoides and oxyuris. While examining the blood to ascertain whether the bilharzia was of not more general distribution through the systemic circulation than had been supposed, he discovered a new parasite, a nematoid hematozoön, a filaria. This worm closely resembled that recently discovered by Dr. Lewis, of Calcutta, in the blood of persons suffering from chyluria, lymph scrotum, or elephantiasis Arabum. Dr. Sousino considers that the filaria he has discovered resembles rather the filaria observed by Dr. Lewis in dogs, than that in man. It wants the external envelope, for instance, and he proposes to name it as a distinct species—Filaria sanguinis hominum Ægyptiaca. The young Egyptian in question presented no symptoms specially suggestive of the existence of a hematozoön; there was neither chyluria, elephantiasis, nor lymphatic varix, all of which are found in Egypt. This discovery gives support to the suggestion that other forms of disease, in hot and tropical climates, hitherto unsuspected of such origin, may ultimately prove to be due to the presence in the blood and tissues of low forms of living organisms.

Dr. Sousino has also recently discovered a new form of bilharzia in the portal vein of a young bull. He proposes to call it "bilharzia bovis," and thinks the discovery may be of importance, by opening the way to the discovery of such prophylactic measures as may avert the disease from man.—*The Lancet*, Aug. 26th.

Case of Tetanus treated with Calabar Bean.—H. W., aged forty-seven, a gardener, received a wound in the web between the thumb and index finger, from a branch of a laurel bush that had been cut off obliquely. The wound was about half an inch deep. It was carefully cleansed and kept open for a fortnight. Sixteen days after the injury, symptoms of tetanus set in, and five days later, on June 16, 1875, he was admitted into St. George's Hospital, under the care of Dr. Dickinson and Mr. Pollock. At that time the symptoms of tetanus were well marked. He was in a condition of opisthotonos, and spasmodic contractions of the muscles of the neck and face, lasting about five seconds, occurred ten or twelve times a day. He was at first put on twelve grains each of chloral hydrate and bromide of potassium, with temporary improvement. On June 19th, however, he was much worse, the spasms recurring five or six times a minute. One-eighth of a grain of extract of Calabar bean was injected subcutaneously every hour, from 11.15 P.M. until 7.15 A.M., on the 20th. After this the spasms occurred at intervals of about two minutes, and were less severe. He felt easier and slept some. On the 22d the injections were given every hour and a half, alternately with a pill containing one-sixth of a grain of the extract. After 10 P.M. the pills and injections were repeated every two hours. On the 24th, the improvement still continuing, the injection was increased to one-fourth of a grain. On the 25th the treatment was discontinued for five hours, but as the spasms become more frequent, it was resumed as before. On the 26th the spasms did not occur, except when the fauces were tickled, and the injection was given only every four hours. On July 1st, the injection was ordered every third hour during the day, and a pill every third hour during the night. On July 3d, there was a slight return of spasms. Two-thirds of a grain of the extract were given subcutaneously every three hours during the day and as a pill at night. On the 4th, one grain of the extract as a pill was ordered every three hours during the night; injection as before. On the 5th the injection was increased to one grain, and the pill to one grain and a half; on the 9th the injection was increased to one grain and a half, and the pill to two grains, given as before. The spasms now stopped, but the patient continued to have some pains in the back for three weeks, and his legs were still weak and stiff on August 18th, when he was sent to the convalescent home. He was seen some months afterwards in good health. —*The Lancet*, August 26th.

Chorea cured by Chloral Hydrate and Bromide of Potassium.—Dr. Sieveking reports the case of a girl, aged twelve, who was admitted into St. Mary's Hospital, London, on February 29, 1876, suffering from chorea. The disease began a month before, three weeks after a severe fright. The symptoms were well marked, the clonic movements involving chiefly the muscles of the arms and neck. She was ordered two drachms of the juice of conium, three times a day, and the quantity was increased three days later to four drachms. On March 10th, the conium was discontinued, as there was no material improvement, but it was given again on the 13th, and continued for four days without benefit. Faradization of the spine and extremities twice a week was then ordered, but after the second application the patient became so much worse that she had to be tied to the bed. She was quieted for the time by chloroform inhalations and morphia subcutaneously, and at the same time ten grains each of chloral hydrate and bromide of potassium were ordered every three hours. Under this treatment she at once began to improve, and four days later the medicine was ordered three times a day. The improvement was now progressive, and on May 23d the patient went out perfectly well, with the exception of occasional slight choreic movements of the hands when under the influence of any excitement.—*The Lancet*, August 26th.

Diseased Milk.—Dr. Payne, medical officer of health for Cardiff, in his last report gives a good description of diseased milk (from foot and mouth disease) from examinations made by Mr. Thomas. In the first stage of the disease the only change consists in the presence of small particles of solid matter-fat in a star-like form. As the disease advances, these star-like masses become larger and larger. This is especially the case if the milk has remained long in the udder. When the disease has attained its height, and the milk-glands, either from sympathy, fever, or local causes, become attacked, the milk generally gives a strong acid reaction, while at the same time the casein is uncoagulated. The casein appears to exist in a modified form, several such samples having withstood the action of strong acids for some time before coagulating. If the milk while in this state be slightly agitated for a short time, masses of fat rise to the surface, and from a pint of milk it is easy to obtain an ounce or an ounce and a half of butter. Healthy milk, if shaken for twice the time, will produce no such amount. The color of the milk when much diseased is yellowish brown, and its strong odor and greater consistency easily distinguish it from healthy milk. If water be added to it when

freshly drawn from the cow, although the color and consistency are reduced, the fatty masses are not dissolved, and are easily recognized. Microscopical examination of the milk reveals its extreme richness, and epithelium in very marked scales. The most marked and constant indication of the disease is the tendency of the apparently healthy fat-globules to congregate in masses. When the globules have agglomerated their shape changes from round to oval, hexagonal and broken-down forms, and the masses are often so dense as to present a black appearance under the microscope.—*The Lancet*, August 26th.

Diffused Melanosis.—Dr. Kirkley, of Toledo, Ohio, reports a case of this rare disease. The patient was a woman, aged thirty-four. Her grandfather is said to have died of carcinoma. In April, 1870, the patient's left eye was enucleated for melanosis. After this she remained well with the exception of periodical attacks of acute dyspepsia, until December, 1874, when she began to suffer from excruciating pain in the right hip, extending down the thigh, the attacks occurring between 2 and 4 P.M. daily. Alternating with this were severe gastric pain and frequent vomiting. In April, 1875, the trochanter became more prominent, the knee semiflexed, and the foot rotated inwards, and the least movement caused great suffering. The liver was enlarged, and two tumors—one as large as an orange, evidently connected with its surface, could be felt in the right hypochondrium. The patient died of exhaustion on April 20th.

At the autopsy five to six pints of a highly colored fluid resembling bile were found in the peritoneal sac. The omentum was somewhat disorganized and completely covered with melanotic deposit. This was also abundant in the peritoneal investment of the intestines, and at isolated places in their walls. The liver extended entirely across the body, was about twice its normal size and weight, and its surface was irregular and nodular. The nodules were harder than the surrounding tissue, varied in size from a small pea to a large orange, were dark colored, and when incised presented the same appearances as the melanotic deposits elsewhere. The substance of the liver was in a state of amyloid degeneration. The tumor felt during life was a large nodule situated on the anterior surface of the right lobe of the liver. The right kidney was somewhat atrophied. The other organs were healthy. The right leg was shortened two and a half inches, and the foot was everted. The neck of the femur was entirely disorganized, could be easily broken down by the finger, and presented the same melanotic character as the peritoneum. The head of the bone and the acetabulum could not be examined. —*Ohio Medical Recorder*, Sept. 1876.

Reduction of Dislocation of the Hip-joint by manipulating the Femur over a Fulcrum in the Groin.—Dr. Sutton recently reduced in this way a dislocation into the ischiatic notch, of four weeks' duration, that had resisted all other methods of reduction. The patient was anæsthetized, and a piece of muslin rolled up into a firm pad between two and three inches thick and about fifteen inches long, and secured by a piece of string, was placed in the groin to act as a fulcrum. The thigh was now flexed over this, and by the leverage thus obtained the head of the femur was raised out of the ischiatic notch, and also high enough to pass over the rim of the acetabulum. The leg was then flexed upon the thigh, and the knee pushed forwards toward the sternum, in order to place the head of the femur on a level with the cotyloid cavity. The knee was then moved outward, and at the same time an up and down movement given to it to break up the adhesions about the head of the femur, and facilitate its return to the socket. While making these movements, which required but little force, the knee was slightly raised, the leg being still abducted, and the bone glided into its proper place. The time occupied in reducing the dislocation was between five and ten minutes. The patient has since recovered.

This makes the fourth case in which dislocation of the femur, after all other means had failed, has been reduced with remarkable facility by manipulation over a fulcrum in the groin. Three of the cases were dislocations on the dorsum ilii, and one into the ischiatic notch. Dr. Sutton claims many advantages for the method, the principal of which is the ease with which in this way the head of the bone is raised out of the ischiatic notch, and over the rim of the acetabulum.—*American Practitioner*, September, 1876.

Gunshot Wound of the Skull; Ball retained seven Years; Operation; Cure.—Dr. Demme, of Philadelphia, reports the following interesting case. In September, 1868, a young man shot himself in the right side of the head with a single-barrelled pistol loaded with several balls. He was unconscious for a considerable time. On the same evening several pieces of bone and a ball were removed. He was in a critical condition for a long time, but finally recovered and returned to his work. He remained perfectly well until June 17, 1875, when he became overheated at work, and complained of a dull, heavy, dizzy feeling in his head. On the same evening he suddenly fell back unconscious, and when seen by Dr. Demme soon afterwards, he was totally unconscious, with contracted pupils, high fever, full, hammering, slow pulse, and dry, hot skin. At the same time there were violent clonic spasms of the entire left side, the muscles of the leg, arm, and left side of face being in constant spasmodic action. Under the use of leeches to the right temple, revulsives to the limbs and spine, and active purgatives, the symptoms rapidly ameliorated. The next day he was conscious, and in a week he resumed work. He now began to suffer from intense neuralgic pain in the head, from which the remedies used gave him no relief. In August he had an attack similar to the above, but less severe. The attacks were repeated every few months, and the pain in the head became almost unbearable. Frequent examinations revealed at the upper end of the furrow caused by the gunshot wound, about half an inch above the ext. aud. meatus, a spot exquisitely tender on pressure, and slightly elevated above the level of the skull. On the 8th of April, an incision was made down to the skull, and this prominence freely exposed. It was found to consist of an irregularly elliptical bony elevation, about five-eighths of an inch in its long diameter. This was cut through with a chisel, and a pistol-ball was found imbedded in the bone, and was with considerable difficulty removed with an elevator. The ball weighs fifty-seven grains. During the four and a half months that elapsed between the operation and the writing of Dr. Demme's article, the patient had had no return of his former troubles, but continued to enjoy excellent health.—*Medical and Surgical Reporter*, September 16, 1876.

A New Journal.—A new Italian journal, under the name of *L'Indipendente*, is being issued in Turin. It will be the continuation of the *Gazzetta Medica di Torino*.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 28, 1876.

THE SANITARY CONDITION OF PHILADELPHIA AND THE EXPOSITION GROUNDS.

As foreshadowed in our editorial of last week, we have taken special pains to make inquiries into the basis of the reports that have been widely circulated regarding the insalubrity of Philadelphia, and especially of the Exposition grounds.

A Commission from the RECORD has spent several days in making a sanitary inspection of those localities where hygienic precautions are said to have been neglected, and in co-operation with several medical men in Philadelphia has gathered sufficient data to form a tolerably intelligent idea of the nature of the affections that have prevailed in and about the grounds this season.

The task has been one of uncommon difficulty, as is usual in such cases; but we are glad to chronicle the results of the investigation, both in justice to our Philadelphia friends, whose grand efforts this Centennial year has been crowned with such unexampled success, and also for the benefit of that small number who may have deferred their visit to the Centennial city until the sanitary state of the case had been fairly presented to them. This, we believe, we can now do with sufficient accuracy for all practical purposes.

We may at the outset sum up a few of the more important facts that have made themselves evident. So far as the sanitary condition of the grounds are concerned, they may be regarded as fairly good. There have undoubtedly been numerous instances of mild affections attributable to irregularities in diet, excessive fatigue, mental excitement, or the influence of the extraordinarily hot weather of the summer, especially among the visitors to the Exposition, but these affections have in almost all cases yielded rapidly under treatment.

Typhoid fever and allied febrile forms have unquestionably been much more prevalent than last year, but the comparative mortality from such causes has been largely surpassed even this year by at least one of the large cities which was visited as usual during the same season by immense numbers from all parts. How justly we have been entitled to the conclusions just given, may best be judged by our readers after a survey of the data from which they have been derived. And first for the Exposition grounds.

To appreciate the task that lay before the engineers in devising effective drainage and sewerage for this new territory, it will be best to consult the map. We shall there see that this three hundred acres of land is skirted on its eastern borders by the Schuylkill river, and that it is traversed from east to west by ravines which would naturally pour their waters into the river as it flows by. This very river water, however, is utilized for drinking and other purposes in the city of Philadelphia; for only a short distance below, at Fairmount, it is pumped up into a supply reservoir. Below this point again the river is dammed, and below the dam it receives much of the city sewage. It is unfortunate that only a small portion of the grounds slopes towards the south, or in the direction of the Schuylkill below the dam, so that it was thought impracticable by the engineers to carry all the sewage in that direction. Upon this southern slope, however, are the Main and Machinery buildings, so that a very large part of the waste really escapes to the southward, and emptying into the Elm Avenue sewer, on the southern line of the grounds, finds its way into the Schuylkill below the dam.

On the rest of the grounds, from the Avenue of the Republic northward, the slope is mainly in an opposite direction, and here it is that the sewage is not carried into the city sewers, but is stored up temporarily in cesspools. This arrangement is thought to be perfectly safe, and the best practicable, because while the soil itself is clay, the subsoil is gravel, and much of the liquid matter passes away through this natural filter. The residue is removed once or oftener daily, by odorless excavator companies, there being between seven hundred and eight hundred dollars paid to these companies per week for their work. They appear to do it well, removing the waste in closed carts. Owing to the excessive use of water for various purposes on the grounds, it was found impossible to provide for all waste in this manner, and a certain amount of the purely fluid matter has been allowed to pass into the two ravines, the Landsdowne and the Belmont, where it mingles with the surface stream. The former is the larger, and is artificial, carrying off the overflow from the principal lakes.

The water for the supply of these lakes is chiefly supplied by the Centennial Commissioners' own mains, the water being pumped up from the Schuylkill at a point intermediate between the outlet of the Belmont and Landsdowne streams, above the dam. In following down the Landsdowne stream it appears clear, and has no odor for certainly more than half its course. Then it receives sewage behind the Restaurant Lafayette, and at a point still lower down the escape from

a urinal. The drains of the walks and drives also empty into it, but in dry weather little or nothing passes them. Arrived at the Hunters' Camp, a short distance from the eastern limit of the grounds, the water is allowed to collect and form an artificial pond, in order to float one or more canoes. Here the water is really turbid, and is covered with scum, and has become a nuisance, giving off foul sewer gases, which above were only slightly noticeable. Instructions are now issued to drain off the pond nightly, by lifting the sluice-gate, thus emptying it entirely. It is then filled up again during the night with fresh water. Notwithstanding, however, the contamination of this water, it is tolerably clear when it makes its first escape. Indeed, it has a fine opportunity to aërate and so oxygenate and purify itself as it dashes down over its stony bed, being tossed hither and thither in its winding way. Most of this contaminated water comes from the restaurants, and is chiefly from the washings of dishes, the minute particles of organic matter suspended in it being mostly from cooked food. Where the little Belmont stream empties, it is said that the force of its fall carries the matter sufficiently far out into the main current of the river, and that as it passes down towards the dam it is prevented from mixing with the water pumped up into the grounds by a long, narrow island which intervenes. The influence of this little stream must, in ordinary times, be very inconsiderable on the quality of the river water, though it is conceivable that heavy rains may carry down a large amount of surface washings. Such solid matter as has not been provided for in the ways already stated, as, for example, kitchen garbage and table waste, is collected in barrels, properly disinfected by the sulphate of iron, Girondin's fluid, or chloride of lime, and removed twice daily. A force of inspectors keeps the grounds under constant surveillance, and authority is given to instantly revoke the license of any establishment not adhering to regulations. It is true that in the latter part of May it was found that the Schuylkill water at Fairmount had become polluted, containing thirty-eight parts per million of sewage. Owing to the exertions of the Chief Engineer, the sewage soon was reduced to three parts per million. According to the more recent reports of Dr. Cresson, the water used in the Exhibition grounds only contain about 1.74 parts per million of sewage, a quantity which is regarded as extremely small. After a rain it is said to be discolored, which is held on good authority to be owing merely to an admixture of clay.

As for the walks and drives, they are kept constantly swept by a gang of about one hundred and eighty men, and the sweepings are carried away; but it is manifestly impossible with the dense crowds in daily attendance to keep that sanitary order which might be wished, for with the great majority of visitors the place is nothing but a huge picnic ground, and when they have disposed of the noon-day lunch brought with them in the shape of bread and cheese, ham, sausages, home-made pies, hard boiled eggs, and the like, they throw the remains where it is most convenient, the result being to clog up the water escapes around the fountains and springs, and were it not for the nettings and gratings, the little streams in the ravines. Notwithstanding, however, these drawbacks, the universal testimony given in answer to inquiries of those employing large numbers of men about the grounds, especially such as have slept there, is that there has been very little sickness among them, indeed no more than in ordinary times and in other places.

We are not prepared to say that the arrangements for carrying off sewage and drainage are all that could be desired; indeed, it is clear that the supply water of the city is contaminated by the sewage of the grounds, but it is contended that the plan adopted was the only effective one that could be devised for the greater portion of the grounds; and, again, that this matter is so largely diluted with ordinary Schuylkill water that the taint is minimal. As for the sanitary condition of the grounds themselves, it is still to be proved that they have caused any unusual disease; and this is the more remarkable when it is considered that the whole soil has but recently been turned over, and has therefore been in that condition which is supposed to breed malarial affections. It is said that there was at one time a form of trouble prevalent that has been called sun-fever or sun-exhaustion. It prevailed extensively at the grounds during the intensely hot weather, many of the military guards being struck down by it; but the patients recovered quickly when removed from the influence of the sun, or after a trip into the country. One practitioner gives a number of instances in which his patients had experienced a continued fever for several weeks, fully half the cases having been affected previously by sun-fever; they had sometimes the rash of typhoid, but not the abdominal symptoms. Those attacked were mostly residents of the city, and were scattered over it in all directions. The type was mild, and all got well.

Ordinary diarrhœal or gastric disturbances have certainly been common, as they are in any places where the visitors are exhausted by fatigue or excitement. There can be little doubt, however, that typhoid fever has been quite prevalent in Philadelphia for some time past. According to the returns of the Board of Health, the number of deaths from this cause in the last week of December, 1875, was 13, or 1.57 per 100,000. Before the opening of the Exposition the Centennial ward (24th) had an estimated population of 11,310, the largest, with but two exceptions, in the city. But, leaving out of account that the actual increase in numbers has probably been greater in this ward than in any other, we find that the rates of mortality have been actually less than in several others. Examining the death returns of typhoid fever for the week ending August 5th, when a very marked

increase in the death rate took place, to the week ending Oct. 7th inclusive, we find that the disease was scattered irregularly over the city, while it showed somewhat of a preponderance (not very marked) in some localities. The highest rate of mortality was in the 29th ward, where it was 73.6 per 100,000, or 25 in a population of 33,974. In the 10th it was 44.3, or 11 in a population of 24,786. In the 20th it was 43.0, or 18 in a population of 41,854; while in the 24th it was only 38.9, or 16 in a population of 41,310.

The conditions of the dense pile of structures just outside the grounds is one that would naturally be thought to invite every form of zymotic disease. We are informed, however, that this whole area is kept under constant inspection by the Board of Health, and no nuisances are allowed. Many of the buildings, however, are said to have no sewer connection. Practically, however, the returns from this whole section, comprising also the Centennial grounds included in the 24th ward, have not shown an increased ratio of mortality over other wards in the city. This also is remarkable, if it is true as claimed, that most of the Centennial employees live in the ward.

Whatever may be the sanitary conditions of the large hotels, their attachés and physicians do not give any clear-cut histories of typhoid fever cases among the visitors, very many of whom have lived there the greater part of the summer. In three of the largest hotels there, no trustworthy evidence could be obtained that the hotel employees had suffered from malarial or any miasmatic disease, excepting from intermittent fever in a single case.

In regard to the health of the city, an inspection of the records in the Presbyterian and Pennsylvania hospitals sustain the official records, and show that there has been a marked increase in the number of typhoid cases, amounting, perhaps, in round numbers to three or four times the usual number at this season. There has also been about an equal increase in the cases classed as typho-malarial. But while those classed as genuine typhoid have been fully as severe as usual, the typho-malarial cases have been quite mild in character.

Through the kindness of one of the medical officers of the Philadelphia Hospital (Almshouse), we have been furnished with some data from that institution, and we insert the results as prepared in tabular form. A comparison is here made between the fever cases admitted during the months of August, September, and October of 1875 and 1876.

1876.

	Total treated during July, Aug., Sept., 1876.	Cured.	Died.	Centennial in origin.	Remaining Oct. 1, 1876.	Patients recd in medical wards, Jan. 1, to Oct. 1, 1876.
Typhoid fever...	16	5	5	2	6	2191
Typho-malarial..	6	4	2	2	1	....
Typhus fever...	..	..	..	..	..	....
Remittent fever.	2	2	..			....

1875.

Typhoid fever...	9	7	2	..	..	2128
Typho-malarial..	4	3	1	..	..	....
Typhus fever...	..	..	..	..	..	....
Remittent fever.	4	4	..	..	..	....

The very large number of patients admitted annually to this hospital furnish us with a tolerably good criterion for deciding on the prevalence in typhoid and other allied affections as compared with last year. It will be observed that the number of typhoid cases had not doubled over last year, that typho-malaria had somewhat increased, remittent diminished, and there had been no typhus recorded. These figures therefore agree with the opinions expressed in the letter from Dr. Pepper, which we insert, though in the other hospitals of which we obtained data, the increase in typhoid was much more marked.

It is well known that typhoid is apt to be prevalent in various sections of the country at this time, and the authorities are inclined to think that much of it is imported by persons who have become poisoned with the disease, which has broken out under the fatigue, loss of sleep, excitement, induced by a visit to the Centennial.

Certain it is that Philadelphia is not the only city that has been so affected, for while the highest death ratio for typhoid was 3.77 per 100,000, which was for the week ending August 26th, we are informed through French statistics, that in Paris the ratio was 4.69 per 100,000 for the week ending August 17th, and a nearly equally high ratio was maintained for several weeks. We take great pleasure in introducing here the letter already alluded to from Dr. Pepper, Medical Director of the International Exposition, written to a member of the RECORD COMMISSION. It speaks for itself, and may be regarded as an authoritative expression of opinion on the part of one who has had unequalled facilities for observation.

We are glad to say that his statements are in the main our conclusions, though in some special localities we appear to have found that the mortality from typhoid was somewhat increased over his experiences.

"In reply to your questions about the general health of Philadelphia during the past five months, and particularly in regard to the prevalence of typhoid or typho-malarial fever, I will make a few brief statements. I enclose a copy of a circular recently issued, from which it will be seen that the general health of Philadelphia during the period named has been exceptionally good. This result, obtained from the official data of the Registrar's office, is confirmed by the records of hospital and private practice. It is, however, undoubted that there has been a larger proportion of febrile affections during a portion of this period than is usual. The forms which these affections have assumed are simple intermittent fevers, typhoid, and typho-malarial fevers, and catarrhal fevers with marked prostration. All alike have been mild in type and amenable to treatment. The typhoid fever, in particular, has been characterized by an absence of severity, and by a tendency, in many cases, to abort at some period during the third week. Care-

ful enquiry has failed either to detect anything peculiar in the forms of disease prevalent this summer, or in the distribution of sickness in the various parts of the city. It has certainly been impossible to trace any specially unhealthy influences in connection with the grounds of the International Exposition, or their immediate neighborhood. It is perfectly well known that probably in consequence of the unfavorable climatic conditions of the past summer, there has been an unusual amount of malarial and typhoid fevers throughout the Middle States since the beginning of August. When we reflect upon this, and upon the vast multitudes—millions in number—who have thronged this city (Philadelphia), during the past five months, it must seem remarkable that such great freedom from disease and so low a rate of mortality should have been maintained. In a number of instances which have come under my own observation, typhoid fever has made its appearance in persons visiting this city so soon after their arrival as to make it evident that it had been contracted on their route. It is unnecessary to remind you of the powerful predisposing influence exerted towards the contraction of all febrile diseases by excessive fatigue, insufficient sleep, excitement, irregular and improper meals, and many other depressing causes. I presume that pleasure-seekers are at all times supremely indifferent to the importance of hygienic rules, but I think that such indifference can never have been more conspicuously displayed than by many of the visitors to the Centennial International Exposition. The great majority of those who have been taken sick during, or consequent upon their visit, have themselves only to blame for it.

"In conclusion, I would repeat that the febrile affections which have occurred in Philadelphia during the past five months have presented no special or unusual features whatever, but have been of the same type as those which have prevailed so widely over the Middle States during the same period; that no special causes have existed here for their development, and that they have occurred here in about the same proportion to population as elsewhere; and that the vast majority of the cases that have occurred have been due, not to any specially unhealthy influences connected with the Exposition Grounds, but to exposure during travelling, or neglect of the laws of health while here."

We feel obliged to offer a few words in explanation of some figures that are contained in the circular referred to in Dr. Pepper's letter. It is shown that in New York there has been a heavier weekly death rate than in Philadelphia—171.9 as against 83.8—from diarrhœal affections and typhoid fever during the summer months of this year. It might be inferred from this that the average typhoid mortality was heavier here than in Philadelphia, while the reverse is the case. Our weekly mortality from these causes has never been as large this season as it has been in Philadelphia, Paris, or Berlin.

What we do suffer from is the diarrhœal diseases of our tenement houses, which do not exist in Philadelphia. The mortality from these causes, which is chiefly among infants in the summer season, makes our rates high for typhoid and diarrhœal diseases, if they are tabulated together. We see no reason, however, to combine them, as typhoid is distinct from many diarrhœal diseases, both in its nature, and perhaps in its cause.

We are not in the possession of sufficient facts to say to our Philadelphia friends that we can account for the increase of typhoid fever among them, for we are not aware how prevalent the disease has been elsewhere; but we may safely say—and this, perhaps, they will themselves admit—they have certain conditions present among them that are generally supposed to favor the production of typhoid, viz.: an impure drinking water and imperfect sewerage.

The water supply, as taken from the Delaware river, is notoriously bad, as any one can testify who has seen the water at the point where it is pumped up. It is not only polluted with the city sewage, but being near the mouth of a sluggish stream, cannot fail to absorb some of the waste which is borne down by the current from the factories and works on its banks.

The supply from the Schuylkill is probably not of such quality as drinking water should be. The river receives the sewage of cities and towns on its banks for miles and miles, and it can therefore hardly fail to be more or less contaminated.

Frequent complaints are made against it by those visiting the city, both as to its color and odor, though it must be confessed that at the present time it appears clearer than the Croton.

As for the sewers and drains, any one passing through the streets will be struck with the fact that an immense amount of waste from the houses runs out in streams down the alleys between the houses, or directly from the houses into the gutters, where it courses along, constituting little rivulets that rush on for considerable distances before they can hide themselves in a culvert. This large exposed surface of foul water, giving off offensive gases, and an impure drinking water, may act as fruitful agents of typhoid and other fevers. Probably, however, they will be harmless to most persons in good health, when ordinary precautions are heeded, which visitors should recognize when away from home. Such care, however, as Dr. Pepper says, is not to be expected of pleasure-seekers.

We have thus endeavored to present the facts of the case as bearing upon the existence and probable causes of fever in Philadelphia. While there is no doubt that the sewerage is very defective, that sewage is mixed to a certain extent with the drinking water, it is pretty evident that the dangers of fever have been very much exaggerated, and that there is very little more risk in visiting Philadelphia than would be encountered in other strange places. To those, however, who wish to take all ordinary precautions, under the circumstances we would simply say: avoid drinking the water, unless it has been boiled; eat warm and nutritious food at accustomed intervals, and guard against over-fatigue, whether of body or mind.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

The last of the series of remarkable gatherings of 1876, in which medical men have been specially in-

terested, was held at Boston, during the first week of the present month. Rather anomalously, the care of the public health comes in as the last link in the chain, after the national, international, and State associations have met and amply discussed the numerous morbid conditions dependent on its total or partial neglect. Like the moral which so frequently adorned the ending of a story, or a poem in days of old, this meeting of earnest sanitarians casts a suggestive reflection over all the centennial medical convocations that have preceded it. It can scarcely, however, be considered a purely medical association, for in its objects it merits, and to a certain extent receives, the cordial sympathy of thoughtful men of the profession. The lawyer and the civil engineer are listened to with pleasure at all the meetings, but the great majority of the members are medical men, who, for some satisfactory cause, usually of a philanthropic character, are desirous that the objects of the association shall be successfully accomplished. There is really no absolute reason why physicians should be more prominent than any other class of educated men in matters pertaining to the preservation of individual and public health. The purposes in view are common to all, and all should and must realize their importance, before the advent of the hygienic millennium, which now seems like the shadow of a dream in the distant future. The medical man, however, recognizes more keenly than any other the intrinsic value of prevention, from the fact that experience and observation endow him with a daily increasing familiarity with the evils associated with the infraction of hygienic laws. This is the chief reason for his interest in the great cause of human health; an interest of a most disinterested kind, which would inevitably reduce his practical contact with disease to a minimum in proportion as the general health approaches its maximum.

Viewing the Public Health Association from the standpoint of the universal interest that ought to be taken in it, we are surprised to find its meetings attended by only a score or two of sanitarians, although these are almost all active workers. It would not be a straining of the truth very far beyond the line of perfect accuracy, to say that almost every one present read a paper or took part in a discussion. We believe that the same remark would have been applicable, if the numerical representation of Hygeia's devotees had been much greater than it was. Many members of the medical profession had already allotted every available moment of time at their disposal, this summer, to attendance on the centennial medical convention, and could not subtract another week's vacation from the cares of practice. Apart from this, however, a great drawback to the numerical success of the Health Association exists in the fact that it is not a representative body, in the same sense that applies to the general medical gatherings of other kinds, from their mode of constitution. It is made up of individual interests entirely; societies or boards of health are not identified with it officially, by delegates appointed by them; and the members merely represent themselves and their own tastes for this work and their appreciation of sanitary reform. In the present heterogeneous composition of local sanitary boards, the existing arrangement is much more likely to inure to the public benefit. Until these boards are made up of as good moral and intellectual material as that which characterizes the great majority of the members of the American Public Health Association, we sincerely hope that they may never have the opportunity granted them of bringing into so respectable a body the intriguing tendencies and machinations of the political rings and parties of some of our large cities. We honestly believe that some of these gentlemen, who assume to look after local sanitary interests, would scarcely feel at home in the novel position they would occupy in the presence of right-thinking, unselfish men, earnestly engaged in the study of the improvement of the health of individuals and communities.

We publish elsewhere a brief abstract of the kind and amount of work done by this association. Many of the questions discussed were of the gravest importance, and have a practical bearing on all the vital interests of health and human happiness. Their constant agitation, from year to year, must yield in due time such fruit as will make the hygienistic heart rejoice, even though the youngest sanitarian of to-day may be gray in the cause before he witnesses the full accomplishment of his cherished wishes.

Reports of Societies.

PROCEEDINGS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

This body held its fourth annual meeting at Boston, October 3d to 6th, inclusive. The officers for 1875-6 were: President, Dr. Edwin M. Snow, of Providence; 1st Vice-President, Dr. John H. Rauch, of Chicago; 2d Vice-President, Francis A. Waller, LL.D., of New Haven; Treasurer, Dr. J. Foster Jenkins, of Yonkers; Secretary, Dr. Elisha Harris, of New York.

Dr. Snow, President, delivered the opening address, in which he particularly alluded to the mountains of ignorance and superstition on the subject of hygiene which must be removed. He also showed how little was known, even by the wisest, of the causes of such diseases as cholera, typhoid fever, etc.

Without dwelling on the details of papers presented, and the points which elicited special discussion in regular order of sequence, we may appropriately examine the work accomplished by the Association under the three divisions of subjects into which the executive committee grouped all the leading discourses, papers, and discussions.

I.—LEGISLATION AND THE APPLICATIONS OF LAW FOR PUBLIC HEALTH PURPOSES.

In this department of the subject of hygiene may be mentioned the following papers, some of which were

ably discussed: Mr. Henry J. Crowell, of Boston, read a paper on "Sanitary Laws to Regulate the Business of Slaughtering, a Necessity," showing many of the evil effects of private slaughter-houses, and commending the abattoir system of concentration, giving a sketch of its various processes. Dr. E. H. Janes, of New York, gave a localized description of the abattoirs of that city, introducing a resolution laudatory of the system, when properly conducted, which was adopted and afterwards reconsidered, and ordered to be printed without endorsement.

An interesting discussion took place on "Expert Testimony in Matters Affecting Life and Health," introduced in a paper by ex-Governor Emory Washburn, of Massachusetts, and participated in by Prof. H. P. Bowditch, of Boston, Profs. Horsford and Ordronnaux, and Dr. L. H. Steiner, of Maryland. The whole subject was ably dissected, and allusion more than once made to the faulty position occasionally assumed by the expert himself, as in the Wharton case, in which one called for the defence claimed to be the representative of one side only. A committee was appointed to inquire into the methods of obtaining expert testimony prevailing in Europe.

Dr. Steiner followed with a paper on "Expert Supervision of the Construction and Internal Arrangement of Public Institutions, in order to prevent Injury to the Health of their Inmates," showing the responsibility of the State in the matter, and the necessity of duly appointed experts who should make thorough inspection and examination.

Dr. Horsford then read a somewhat jocose paper on the necessity of having a house-physician to look after the ailments in every part of the house, resulting from neglect of duty by the plumber, carpenter, etc., to be regularly consulted and paid, just as any other physician would be.

Rev. E. E. Hale spoke of the evils of crowding people together; the laws on the subject were not strict enough. He said that the poet Horace's statement, that death knocks impartially at the palaces of kings and the hovels of beggars, was one of the greatest falsehoods that unveracious poet ever uttered.

Dr. Austin Flint read a paper on "Food and its Relations to Personal and Public Health," arguing that drugs could never take the place of food; that there was no rule as to the amount of food required for any individual outside himself; that the natural desire for food should always be satisfied, and at once; that in all cases the appetite was more trustworthy than the usual arbitrary dietetic regulations, which were sure to lead to bad results.

Prof. J. D. Runkle, President of the Institute of Technology, referred to the "Improvements in the Health of Students." They were not overworked; neither was their health improved after the curriculum was changed. Dietary imprudences were the real causes of impaired health.

J. H. Shedd, C.E., of Providence, read a paper on "Water Supplies for Large Institutions and Small Communities," giving the amounts required, consumed, and wasted, with the characteristics of a good water supply.

Dr. A. L. Gihon, U.S.N., read an essay on "Sanitary Reform on Shipboard," urging an inquiry as to the feasibility of the government regulating the sanitation of men-of-war, passenger and merchant ships, by sanitary inspection on arriving and departing.

Dr. J. M. Woodworth, Supervising Surgeon General U. S. Marine hospital service, then read a paper on the "safety of ships and those who travel in them." He described the sanitary architecture of vessels, and gave very interesting statistics of the losses of life by casualties on shipboard, with special mention of the amount of work done by the Government for the protection of ships and their inmates, and the saving of life.

Mr. Henley, of London, gave an account of "Sanitary Laws and Regulations in Great Britain," showing their satisfactory working.

Mr. Charlton Lewis, of New York, in a paper on "Ancient and Modern Hygiene," showed that increased longevity at the present day was due to greater care of infant life, of the sick and infirm, avoidance of epidemics and of famine, etc.

Dr. J. S. Billings, U.S.A., argued, in a paper on the "Rights, etc., of the Community in regard to Public Health," in favor of the right to enforce measures, even to the invasion of personal liberty.

Col. G. E. Waring and Dr. Ezra M. Hunt, of New Jersey, examined respectively into the "Sanitary Condition of Country Houses and Grounds," and the "Sanitary Appointments of Dwelling-Houses."

A number of valuable papers were read by title.

II.—DANGEROUS EMPLOYMENTS AND HARMFUL PROCESSES.

Dr. E. S. Wood, of Boston, Mass., read a paper on "Illuminating Gas and its Relations to Health," giving an account of the method for procuring greater purity.

Dr. L. F. C. Garvin, of Rhode Island, presented a paper on the "Causes of Accidents in Large Factories," with a list of proposed remedies, such as legal prohibition of the employment of children, enclosure of points of danger, warning to the inexperienced, etc., and the following resolution offered by him was adopted:

Resolved, That the due protection and welfare of factory operatives require: 1. Half-day schooling for children under sixteen years of age; 2. Uniform hours of labor, not exceeding sixty per week; 3. Frequent inspection of the mills and tenement-dwellings of factory villages, and of the milk sold to the inhabitants, by an authorized public health officer.

Prof. W. H. Brewer, of Yale College, presented a paper on "Gases of Decay and the Harm they cause in Dwellings and Popular Places." Sewer gas acted in some deleterious way unknown to chemistry. He examined the mode of production of harmful gases, and their mode of producing disease.

III.—TOPOGRAPHICAL AND SANITARY SURVEYS, AND OTHER SYSTEMATIC WORKS FOR PUBLIC HEALTH PURPOSES.

Mr. James T. Gardner, C.E., read a paper on the relations of such surveys, etc., to public health, showing the action of the earth's surface as a cause of disease, etc.

Dr. J. M. Jones, of Washington, D. C., read a paper on "Suggestions for Increasing the Water Supply of Cities, and to Encourage its Free Use as a Sanitary Measure," in which he urged the necessity of providing against inadequacy of supply in the future, and of supplying vastly greater quantities of it to secure improved hygienic conditions.

The Committee on Proposed Sanitary Survey of the United States reported progress, and their plans of future operations.

The following officers were elected for 1876–1877, the next meeting to be held in Chicago: President, Dr. John H. Rauch, Chicago; First Vice President, Dr. L. H. Steiner, Maryland; Second Vice-President, Dr. E. M. Hunt, New Jersey; Treasurer, Dr. J. Foster Jen-

kins, New York; Secretary, Dr. Elisha Harris, New York; Executive Committee, Dr. John M. Woodworth, Surgeon General, Marine Hospital, Dr. John S. Billings, U.S.A., Dr. Jackson S. Schultz, New York, Dr. A. L. Gihon, U. S. N., and Dr. Charles F. Folsom, Boston.

Resolutions were passed of sympathy with the medical men of the South, and with those localities now suffering from yellow fever; and asking an investigation into the causes. After resolutions of thanks, etc., the Association adjourned *sine die*.

Correspondence.

ANTISEPTIC HERNIOTOMY.

To the Editor of The Medical Record.

Sir:—Lister's recent presence in our midst, and his earnest championship of the antiseptic methods which he has so long advocated, would seem to justify a report of the following case, in which every step of the operation was in strict accordance with his teachings, his own spray-producer and antiseptic dressings employed, and the result an entire success, although the operators had not previously made use of the method.

In May last, Mr. ——, living out of town, slipped while running. The right testicle of this gentleman had never descended into the scrotum. Its habitual position was just outside of the external ring, or within the inguinal canal. He had found it impossible to wear a truss, and had never had hernia. In slipping he fell, and a swelling appeared in the groin above the testicle, attended by pain, nausea, and signs of strangulation. Reduction was impossible. The symptoms of strangulation slowly disappeared, and for domestic reasons an operation for the relief of the painful incarcerated hernia was postponed until the autumn.

Oct. 9th, under the carbolic spray, the tumor was cut down upon by Dr. Van Buren and myself, Dr. Stimson assisting. The testicle was found to be atrophied, the tunica vaginalis communicated with the peritoneal cavity, and contained a piece of omentum as large as a pullet's egg, bound fast by firm adhesions. These were torn and cut away, but reduction was still impossible, without calling for such an enlargement of the internal ring as seemed unadvisable. The neck of the pediculated lump of omentum was therefore tied with carbolized catgut, cut off, and the stump and ligature reduced through the internal ring into the abdomen. The spermatic cord was tied with carbolized catgut, the atrophied testicle removed, the wound closed with catgut sutures, and the proper dressing arranged with an antiseptic spica bandage.

Oct. 10th, at night the pulse reached 102 and the temperature in the mouth 100⅗. The next day pulse 92, temperature 99⅘. Oct. 12th the patient sat up in bed, pulse 88, temperature 98⅗, and so on. On the fourth day the patient eat his beefsteak as usual. On the sixth there was a copious evacuation of the bowels. On the seventh the parts were entirely healed, except a little subcutaneous pouch above the scrotum, where a piece of catgut ligature which had not been absorbed remained attached to the stump of the spermatic cord. No further antiseptic dressings were used. The patient got up and walked a little on the eighth day. About three grains in all of bimeconate of morphia were given through the week, and a half-grain suppository at the time of the operation—no other medicine whatsoever. A truss was applied during the second week, and the patient authorized to go out of doors.

E. L. Keyes.

210 Madison Ave.

HISTORY OF THE NERVE THEORY OF HAY FEVER.

To The Editor of The Medical Record.

It seems to be a part of the law of evolution, as applied to the progress of all new truths in science, that they are received at first with indifference; secondly, with ridicule; and thirdly, with contests in regard to priority. The nerve theory of hay fever having passed through the first and second stages, appears to already have advanced sufficiently far in the third to be twice criticised for not being original with its author.

In the last issue of the Record, Dr. Neftel claims to have suggested and used galvanism for ordinary asthma before I had suggested or used it for hay fever. His statement is doubly erroneous: 1. If the nature and symptoms of hay fever were as well understood by the profession as I hope in a few years they will be, it would be unnecessary for me to state in reply that asthma is but one of an immense number of symptoms that belong to hay fever, and that it is not found in all the cases.

2. Galvanism was used for ordinary asthma long before Dr. Neftel or myself was born. It was used scientifically, and in some cases successfully, by that famous experimenter in electricity, Dr. Wilson Phillips of England, in the early part of this century.*

Yet further, there is little evidence as yet that the special symptom of asthma that complicates many cases of hay fever yields to galvanic treatment as well as ordinary asthma; but on this point more facts are called for. It is certain that nitrite of amyl, that answers so well in ordinary asthma, has thus far failed in the asthmatic symptoms that accompany hay fever, the reason being, I suppose, that in hay fever the exciting causes are constantly acting.

In a recent issue of the *Boston Medical and Surgical Journal*, a reviewer admits that the nerve theory accounts for the phenomena better than any other hypothesis, but intimates that I should have given credit to Dr. Wyman for his suggestions on the relation of the nervous system to the disease. The original suggestion that hay fever might in some cases be a nervous disease was made by Dr. Pirrie of England, in his work on hay asthma, published in 1867. Dr. Pirrie thought there were two forms—one affecting the mucous membranes, the other nervous; but this decision is unwarranted. Moreover, Dr. Pirrie added no new facts or reasonings on the subject, and did nothing to develop the nerve theory. For the single suggestion he deserves credit, and he received it in my work. But in science it has long been established that theories are rarely or never developed and made fruitful by those who, in a dim and uncertain way, originally suggest them. The Darwinian theory of natural selection, as is now acknowledged in Europe, was originally

* See Noad's Lectures on Electricity: London, 1844, p. 240, quoted in Beard and Rockwell's Medical and Surgical Electricity, first edition, p. 598. The last quotation is as follows: "By transmitting its influence (galvanism) from the nape of the neck to the pit of the stomach, he gave decided relief in every one of twenty-two cases, of which four were in private practice, and eighteen in the Worcester Infirmary. The power employed varied from ten to twenty-five pairs."

From that early period to the present moment no *recorded* advance has been made in the galvanic treatment of ordinary asthma. What new methods have been discovered and have been kept secret with the discoverers, I have no means of knowing.

suggested by Dr. Wells of South Carolina; but if a Darwin had not lived, the suggestion would have died with its originator. The history of medicine is filled with major and minor analogous cases.

So far from corroborating in the main the views of Dr. Wyman, as the above mentioned reviewer declares, our conclusions are diametrically opposed. Dr. Wyman regrets that he knows nothing of the nature of hay fever; makes a distinction between the rose-cold and autumnal catarrh; says the disease is confined within definite geographical limits. On the other hand, I claim to have established by a combination of inductive and deductive investigations, that hay fever is essentially a neurosis; that there is no distinction between the early and later forms; but that all forms, whether occurring in June, or July, or August, or September, or in the winter, in this country or in any country, are one disease; that it is found in all or nearly all parts of this country, and that many of the so-called exempt regions, as shown on maps, are filled with hay fever.

Two books more unlike in their leading conclusions were never written.

G. M. Beard.

METROPOLITAN PRACTITIONERS AT WATERING-PLACES.

To the Editor of The Medical Record.

Saratoga Springs, Oct. 6, 1876.

Sir:—Your editorial article in the Record of Sept. 23d, entitled Rural Practitioners and Metropolitan Physicians, refers in such a manner to the letter from a Saratoga physician, that I seem invited by you to explain my position as to certain allegations in said letter, which you state I have acknowledged my willingness to substantiate. I am even more called upon to do this, by your presumption, that I am probably misinformed in regard to the facts, for in that case I must have stated what is untrue. Of the principle discussed in your editorial, and your distinction between the metropolitan practitioner of high standing and the typical hotel physician, allow me a passing notice. To the first, with such professional characteristics as command respect and esteem, we accord all you have to say; and in describing the latter, you have pictured the genus referred to, in the letter from your Saratoga correspondent; for the letter *particularizes* those who "come with an eye to business, and lose no opportunity to publish their presence in our midst." To these alone the article refers, and there follows certain statements elucidating some of the various ways in which the position of typical hotel physician was sustained. It is with these statements I have to deal, and it is not surprising that emphatic denial is given to them, for none can suppose that individuals would be willing to claim proprietorship in such unpalatable exposure. That none of the so-called "charges," in the opinion of the gentleman who interviewed me, were sustained, is not surprising; for it was useless to discuss statements of such a nature, with one whose purpose it was to give them denial. Personal explanations are not most pleasing in the columns of a public journal, but as I am called upon by yourself editorially, and by the appearance of a personal letter in the Record of Sept. 30th, I beg your indulgence.

The statement that, in the knowledge of the writer, M. C. E. is the only man who is generally talked of and admitted to be a "hotel physician," is entirely gratuitous.

The writer then refers to his personal connection with the matter, and after alluding in general terms to what he calls the "charge," and stating that the number of metropolitan practitioners in Saratoga was so small their names must be known to the profession in New York, and concealment would be useless, comes to the so-called specific point. That my authorship of the article was in any sense of the word denied is false, and the writer of the assertion could hardly believe his own statement, when, if he reflected at all, he must have known the name of the writer was in possession of the Editor of The Record. First, as to requesting permission to put up a sign in one of the hotel offices. The writer asserts I denied to him that he was referred to, while Dr. J. is positive I stated to him the contrary. By one of these gentlemen I have certainly been misunderstood, and that there may be no further uncertainty on this matter, I now state emphatically that I did not refer to Dr. Lente—that I never made such a statement publicly or privately in regard to him, but referred to another M.D. then practising here; and I do hereby certify that one among my other authorities for this statement in regard to the hotel sign, is the very writer of the article of denials. Second, as to the finding of the card. The writer assumes that this is "too absurd for any one to notice;" and yet, if it *was* found, it was "placed there by some one interested in injuring me, or in bringing discredit on—all of us." It is unfortunate for the writer that he had no better control over his cards, so as to prevent their indiscriminate distribution, and as no assertion has ever been made that he placed it in its unfortunate location, it is surprising that he can take no other view of the subject than is involved in his ungentlemanly innuendo. The circumstances connected with the card are as follows: The patient was under the professional care of Dr. J. G. Bacon, of this village, and at one of his visits the patient handed a card to Dr. B., on which was the name of our worthy writer and his then present location, which the patient stated he found sticking in his door, having been placed there during his temporary absence from his room, and I herewith submit to you, Mr. Editor, the certified statement of Dr. Bacon in regard to this matter, which you may publish or not, at your pleasure.

Lastly, in regard to "circulars." On referring to the letter from your Saratoga correspondent, you will find these words: "Another heralds his presence here by circulars, and announcements in the journals of the date of his coming and departure." The writer then alludes to my reference to a notice in the *Medical News and Library*, which he terms "a friendly notice by the editor, of my removal to Florida." Will you, Mr. Editor, please refer to the November number, 1875, of this monthly. If that is "a friendly notice of my removal to Florida," it is geographically unfortunate for the gentleman that it distinctly heralds this practitioner's presence in future at the Grand Union Hotel, Saratoga Springs, where he may be consulted professionally." If you will refer to the July number, 1876, of the *American Journal Med. Sciences*, you will there find an article on Spasm of the Heart, which the writer is pleased to date as follows: Saratoga Springs, June to Sept.; Palatka, Fla., Nov. to May." On referring to the number of the Medical Record, July 8, 1876, you will find an account of two cases of severe compound fracture, with remarks, which the same writer is pleased to date "Saratoga Springs, June to September, 1875.") If this is not heralding his location and announcing the date of his coming and departure, what, may I ask, is it? Is it not a special form of professional advertising, and an an-

nouncement to the profession, which might possibly throw in his way more or less professional business that would not come to him if he assumed the position of the metropolitan practitioner, relying upon his reputation; for, as you justly remark in your editorial article on this subject, "such men do not need to advertise their presence in hotels."

Respectfully yours,
R. C. McEwen.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Oct. 15th to Oct. 21st, 1876.

Woodhull, A. A., Assist. Surgeon. Promoted Surgeon, with rank of Major, to date from Oct. 1, 1876, vice Millhau resigned. G. O. 103, A. G. O., Oct. 13, 1876.

Ainsworth, F. C., Assist. Surgeon. Assigned, temporarily, at Fort Vancouver, W. T. S. O. 134, Dept. of the Columbia, Oct. 9, 1876.

Comegys, E. T., Assist. Surgeon. To proceed to Washington, D. C., in charge of an insane soldier, and upon completion of this duty, avail himself of his leave of absence. S. O. 187, Dept. of Texas, Oct. 9, 1876.

Crampton, L. W., Assist. Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 196, Dept. of the Gulf, Oct. 13, 1876.

Burton, H. G., Assist. Surgeon. Assigned to duty at Camp Bowie, A. T. S. O. 122, Dept. of Arizona, Oct. 4, 1876.

Dr. A. G. Walters, of Pittsburg, Pa.—Dr. A. G. Walters died of pneumonia, at his residence, October 14, 1876. The deceased was sixty-five years of age, was a native of Prussia, and a graduate of the University of Berlin. He went to Pittsburg in 1841, where he soon acquired a brilliant reputation as a surgeon.

Dr. Jules S. Thebaud,—Dr. Jules S. Thebaud was fatally wounded on the 11th of the present month, by the explosion of a cartridge for a breech-loading rifle that he was preparing. A portion of the brass from the cartridge embedded itself in the lung, while a projecting point lacerated the heart. The peculiar position and nature of the wound precluded all idea of saving his life from the first. He lingered in great agony for nine days. He died October 20th, in the forty-ninth year of his age. Anodynes were administered to him by his attendant physicians, Drs. Sands, Reynolds, and Stimson, but never to any great extent at his own desire. The deceased was frequently visited in his illness by Cardinal McCloskey, the Vicar-General, Father Quinn, and the venerable Thurlow Weed.

The deceased was born at Morristown, N. J., on the 28th of October, 1827. He came of old Knickerbocker stock, his father being a member of the old firm, in this city, of Bouchaud & Thebaud. He graduated at the College of Physicians and Surgeons, and, while till young, gave promise of being an honor to his profession, a promise so well fulfilled in after life. Leaving New York, he walked the London, Paris, and Vienna hospitals for several years. In 1851 he returned to New York, and established himself in Leroy place. From the first the deceased was fortunate in practice, and having ample opportunities for the cultivation of his taste for surgery, soon became a skilful operator. His contributions to medical literature, although not voluminous, were always valuable and practical. He was connected at different times with nearly all the hospitals in the city. He was also attached to the Catholic Orphan Asylum, the Foundling Asylum, St. Vincent's Hospital in Eleventh street, and the Colored Home. He leaves a widow and eight children. The funeral services were held at St. Francis Xavier's Church, to which he belonged for many years. The interment took place at Calvary Cemetery.

Officers of the Medical Society of the County of New York.—At the seventy-first annual meeting of the Medical Society of the County of New York, held October 23, 1876, the following officers were elected:

President—Dr. John C. Peters.
Vice-President—Dr. Isaac E. Taylor.
Recording Secretary—Dr. A. E. M. Purdy.
Corresponding Secretary—Dr. F. A. Castle.
Treasurer—Dr. H. P. Farnham.
Censors—Drs. Charles W. Packard and E. H. M. Sell.
Delegates to New York State Medical Society—Drs. R. F. Weir and A. McL. Hamilton.

The following gentlemen were elected members:—Drs. B. C. McIntyre, H. Petershausen, E. C. Mann, C. H. Atwater, D. R. Burrill, E. C. Spitzga, J. C. Davis, J. B. Taylor, and A. L. Ranney.

Dr. H. S. Piffard introduced the following resolution, which was referred to the Comitia Minora:

Resolved, That the Medical Society of New York recommend to its members the adoption of the metric system in writing prescriptions.

Remarks upon the resolution were made by Drs. Piffard, O'Sullivan, Castle, and Sell.

Dr. Victor de Méric, the well-known surgeon and writer, who died recently in London, was an Alsatian. Having established himself in London upwards of thirty years ago, he succeeded by talent and strong force of character in securing a high position among his professional brethren, and also an excellent *clientèle*. He was for a long time upon the editorial staff of the *Lancet*, held several hospital appointments, and latterly was President of the Medical Society of London.

Assaulting a Quack.—An outraged patient of a London quack, in lieu of taking satisfaction out of the principal, assaulted the assistant, and was fined therefor 40s. Although it was brought out in evidence that the defendant was a notorious quack, the duped patient had no redress.

Original Lectures.

LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

LECTURE IV.

TYPHOID FEVER (CONTINUED).—SYMPTOMS.

GENTLEMEN:—I will continue the history of typhoid fever, and describe more in detail those variations in temperature which attend its development and mark its progress. As has already been stated, the temperature at the commencement of a typical case of this fever is characterized by morning remissions and evening exacerbations; and by these regular variations often you will be able to make a diagnosis during the first week of the disease. In order to estimate the real value of these variations, it will be found convenient to divide the fever into four periods which shall correspond to the four weeks of the disease.

Usually, the temperature begins to rise about noon on the first day of the development of the fever, and continues so to do until between six and eight o'clock in the evening, when it reaches its maximum height for that day; then there is no change until midnight, when it begins to decline, and by six or eight o'clock in the morning it has reached its minimum decline, which is a degree higher than on the morning of the preceding day. After six or eight o'clock in the morning the temperature does not vary much until noon; then it again begins to rise, and by six o'clock in the evening it has reached its maximum elevation for that day, which is two degrees higher than on the evening of the preceding day. Again, at midnight it begins to fall, and by morning it has fallen a degree, which leaves the minimum temperature for the day a degree higher than on the preceding day. Thus, it rises a degree each day, with regular morning and evening variations, until the eighth day of the fever, when, in most cases, it has reached its maximum height. During the *second week* the temperature remains at about the same maximum degree which it has reached by the end of the first week. There are morning and evening variations of a degree or more, but the maximum of the evening exacerbation remains the same.

During the *third week* the remission becomes more and more marked, and with it the temperature falls, while during the exacerbation the temperature retains the same standard as during the second week. By the end of the third week the morning temperature during the remission will have fallen two or three degrees below the point which it had reached during the second week.

By the time the *fourth week* is reached, or at least by the middle of the week, the temperature becomes intermittent, and with each exacerbation gradually falls lower and lower, until by the end of the week the normal standard of temperature has been reached—it may fall a little below the normal standard.

These are called the typical variations of typhoid fever, yet they are not always present; besides, there are many things which will materially modify them. For instance, marked deviations from the record may be produced by complications which would never have been discovered but for the irregular thermometrical variations. By treatment, for a time the temperature can be very much lowered; but, if the treatment be discontinued, it will again rise. In some cases you will be unable to ascertain the cause of the irregularity.

PULSE.—The pulse is also subject to variations, which correspond very nearly with the variations in temperature, and occur not only on different days, but at different hours on the same day. During the first week the pulse becomes more and more frequent, during the second and third weeks it remains at its height, and during the fourth week sinks to its normal average. During the whole course of the disease it is less frequent in the morning than in the evening.

If, at the commencement of the fever, the pulse is ninety-eight, it gradually increases in frequency, until by the end of the first week it has reached one hundred or one hundred and ten per minute; during the second week it remains at about this height; after that time, it may run as high as one hundred and twenty or one hundred and forty. During the first and second weeks the rate of the pulse and the temperature range correspond, but after this time the parallelism ceases, the failure of heart-power beginning to manifest itself. This failure of heart-power is indicated by an increase in the frequency and feebleness of the pulse, which at this time may reach one hundred and forty per minute, and yet the temperature show no alarming variation. A pulse which remains for five or six consecutive days above one hundred and twenty per minute is a bad omen, for it shows extensive changes in the muscular tissue of the heart. Under these circumstances, the pulse may become irregular and intermitting. Should these irregularities and intermissions occur during the third week, in most cases they are followed by death. With an irregular and intermitting pulse, usually, you will find the first sound of the heart inaudible over the precordial space, and this indicates that prompt and judicious means must be employed to restore, if possible, the heart's normal action, and thus relieve your patient and avert a fatal issue.

The severity of the fever during the first and second weeks of its development is, to a great extent, determined by the frequency of the pulse and the height of the temperature. Although delirium and extensive tympanitis are important symptoms, yet they do not determine the result; but if your patient during the first, or at the commencement of the second week of the disease, has a pulse of one hundred and twenty per minute, and a temperature of one hundred and six, it is very doubtful whether convalescence can ever be established.

You must remember that from feeble heart-power alone the pulse may increase in frequency while the temperature is steadily falling. On the other hand, the pulse sometimes falls almost to a normal standard, while the temperature remains high. In either case, if these changes occur during the second or third week of the fever, they must be regarded with suspicion.

ERUPTION.—We now come to the study of what is known as the "characteristic symptom" of typhoid fever—namely, the eruption. Some have claimed that the eruption should be considered as a lesion of the disease, but I prefer to class it among the symptoms. It makes its appearance between the sixth and twelfth day (dating from the commencement of the fever, not from the day the patient takes his bed, but from the time the first symptoms of the disease manifest themselves), and it is not attended by any unusual sensation.

It remains visible from eight to fourteen days, leaving no stains or mark on the surface after its dis-

appearance. It consists of isolated lenticular spots scattered more or less abundantly over the surface of any part of the body, yet usually most abundant upon the chest and abdomen. There may be only a few spots visible at a time, or it may be so profuse as to cover the body like a rash. Two or three well-defined spots of the eruption are sufficient to establish the existence of the fever. Each spot is circular in shape, and varies in diameter from a point to a line and a half, rarely reaching two lines. It is slightly elevated above the surface of the surrounding cuticle, is of a bright rose color, disappears upon slight pressure, and returns as soon as the pressure is removed. Each spot remains visible for three days, and then disappears. Sometimes, as one crop of the eruption disappears, another is developed, and this may go on for eight, twelve, or fourteen days. There are many cases in which only one crop appears. As soon as one spot makes its appearance, it is well to mark it with tincture of iodine or nitrate of silver, so that you may be certain that your observations are always made upon the one point. If it is a spot of typhoid eruption, and one crop of eruption is to follow another, it will disappear within three days from the time at which it was first seen, and other spots will take its place. It is this feature which distinguishes the typhoid eruption from that of all other fevers.

The question may be asked, is this eruption essential to the diagnosis of typhoid fever? Doubtless, there is no question in connection with its history which has given rise to more discussion than this. As a matter of course, this question has two sides. Many observers mention that the eruption is not constant, and consequently not necessary for its diagnosis; while others, equally competent, maintain that unless the eruption be present at some period during the progress of the disease, the diagnosis of typhoid fever cannot be made with positiveness. Jenner states that he found the eruption present in one hundred and forty-eight out of one hundred and fifty-two cases. I would not say that it is possible for typhoid fever to occur without the eruption, neither would I affirm that scarlet fever ever exists without the characteristic rash of the disease; but I do say that, as regards these respective fevers, I would make the diagnosis with equal hesitancy in the one case as in the other.

The eruption is usually most marked in cases of typhoid fever which occur between the ages of ten and thirty. Before ten and after thirty years it is usually not as well marked, and may be readily overlooked unless careful search is made.

I have now described to you the prominent symptoms which are present during the course of a typical case of typhoid fever, yet I believe I have given you sufficient detail to enable you to recognize the disease and to manage intelligently your typhoid fever patients.

At this point let me state to you that the typhoid poison in its operation on the human body does not always effect the series of changes and symptoms which I have been describing. On the contrary, there are cases which run so mild a course that they can scarcely be dignified by the name of fever; besides, there are imperfectly developed cases which show a great diversity in their course, but they all can be included under two heads:

First.—Mild typhoid fever, in which the symptoms are all mild.

Second.—Abortive typhoid fever, in which the duration of the disease is markedly shortened.

In the *mild type*, the fever runs its regular course, but it is of low grade. The temperature rises regularly until its maximum is reached, which rarely exceeds 103° F., then it remains stationary for a time, generally about a week, then a decline follows in the same manner as was noticed in the typical case. This is the regular course of these cases if left to themselves, and, as a rule, they should be left to themselves. Some of these cases are so mild that the patients are not confined to the bed, nor even to their rooms, and perhaps throughout the entire course of the disease are able to transact a certain amount of business. Such cases have been called "walking cases" of typhoid fever.

The eruption appears in these cases early, is of short duration, only a few spots appear; usually there is only one crop. Diarrhœa is also present in most cases of this class, but it is of a mild type, the discharges from the bowels apparently giving relief to the patient. In some cases the diarrhœa alternates with constipation, or constipation may be present throughout the entire course of the disease, and the cases go on exhibiting a varying amount of fever from twenty to thirty days, until gradually convalescence is established. This class of cases, if properly managed, rarely prove fatal; but, if improperly managed, there is great danger. For instance, if a patient walks about while he is suffering from one of these so-called mild attacks of typhoid fever, he does it at great risk to life—in other words, there should be no "walking cases" of typhoid fever. A patient sick with typhoid fever, however mild the type, should take to his bed and remain there until convalescence is fully established, as it is impossible to say just how extensive the changes may be that have occurred in the intestinal track, and in the mildest type of the disease they may be of such a nature that very little physical exertion will cause intestinal perforation, which will be followed by a fatal peritonitis.

The *abortive form of typhoid fever* is ushered in with all the symptoms of a typical case—headache, lassitude, pain in the limbs, nausea, etc., and the temperature during the first week follows the regular variations of the fever. At the onset the disease has every appearance of a severe form of typhoid fever; the temperature may rise as high as 105° F. or 106° F. by the end of the first week; delirium is often active, and diarrhœa is present. By the end of the second week, certainly by its close, the fever is cut short, and abruptly disappears; the temperature falls to the normal standard, and the patient passes on to a state of rapid and complete convalescence. The eruption, diarrhœa, and all the urgent symptoms of the disease may be present, and yet before the end of the second week the patient may have fully convalesced. That it is the typhoid poison which thus acts upon the system, and gives rise to the characteristic symptoms of typhoid fever in these abortive cases, is evidenced by the fact that at the post mortem examinations the characteristic typhoid intestinal lesions are found, and these, taken in connection with the presence during life of the typhoid eruption, establishes the diagnosis beyond question. There can be no doubt but that an individual may be affected, overwhelmed, as it were, by typhoid poison, and yet not develop well-marked typhoid fever. So, if only a moderate amount of typhoid poison is introduced into the system, a mild or an abortive type of fever will be developed. The natural powers of the individual to resist the action of such poisons must always be regarded, and should be taken into consideration, in the treatment of a case.

Differential Diagnosis.—In a typical case, after the fever is fully developed, the diagnosis is not difficult.

The presence of febrile excitement, marked by evening exacerbations and morning remissions, headache, diarrhœa, abdominal tenderness, and other abdominal symptoms, and the presence of the characteristic rose-colored spots, are sufficient for a diagnosis.

In the mild type of the disease, or when the symptoms are developed irregularly, or during the first week of a typical case, the diagnosis is often difficult, and sometimes impossible. The principal diseases which are liable to be confounded with typhoid fever are typhus and relapsing fevers, typho-malarial fever, acute tuberculosis, pyæmia, septicæmia, pneumonia, and gastro-enteritis.

The points of differential diagnosis between typhoid and typhus, relapsing and typho-malarial fevers, will be more apparent and more readily comprehended, after we have studied these different forms of fever. I shall therefore call your attention to their differential diagnosis, after I have given you a history of these fevers.

Acute Tuberculosis.—This disease is attended by very many of the symptoms which are present, and by some supposed to be characteristic of typhoid fever. The fever of acute tuberculosis is of a remittent type, attended by evening exacerbations and morning remissions, delirium, a dry, brown tongue, a tendency to stupor, great prostration, rapid emaciation, and sometimes by a diarrhœa, with abdominal tenderness and tympanitis. All of these are among the prominent symptoms of typhoid fever; consequently these two diseases are frequently mistaken the one for the other. More than once have patients in Bellevue Hospital, with the diagnosis of typhoid fever, presented at the post-mortem examination the characteristic lesions of acute tuberculosis. If, therefore, patients with acute tuberculosis may go through a large general hospital, under the observation of diagnosticians, who certainly are not men of inferior ability, and be supposed to have typhoid fever, there evidently is great danger of a mistake in diagnosis.

The higher range of temperature in acute tuberculosis than in typhoid fever is one of the distinguishing characteristics of the disease. Usually, early in the progress of the disease, it reaches 106° F. or 107° F., while in typhoid fever the temperature rarely reaches 106° F., and almost certainly does not range so high until the end of the second week of the fever, by which time you will have been able to determine the true nature of the disease. Again, you will notice that there is no eruption, neither is there enlargement of the spleen in acute tuberculosis, while both are very constant attendants of typhoid fever; yet their absence is not positive proof that typhoid fever does not exist.

In all doubtful cases you must take into account the family history of the patient, his immediate surroundings, whether typhoid fever is prevailing at the time, and whether the patient has been exposed to typhoid poison. These are important points, and by a careful study of them, if you are able to watch the case throughout its entire course, probably you will arrive at a correct diagnosis before the end is reached. Should you see the case during the first week of the disease, rely upon the presence of the rose-colored spots for a diagnosis of typhoid fever, and you will rarely mistake it for acute tuberculosis.

Pyæmia and Septicæmia.—These diseases, while developing, present many symptoms which resemble those of the developing stage of typhoid fever. In most cases you will be able readily to recognize them, as the surface of the body has a jaundiced hue; there are no lenticular spots, and the febrile symptoms are irregular in their development. There are exacerbations and remissions, but their appearance and disappearance are not marked by any regularity, and usually there is more than one exacerbation and remission in the twenty-four hours. Not only are the variations in temperature irregular, but the temperature reaches a high degree much sooner, and ranges higher throughout its entire course in pyæmia and septicæmia than in typhoid fever. In pyæmia and septicæmia you will also have early in the disease profuse sweatings, great prostration, rapid emaciation, delirium, subsultus, tympanitis, and diarrhœa, while in typhoid fever these do not come on until late in the disease. Besides, the history which precedes and attends the development of pyæmia and septicæmia widely differs from that of typhoid fever.

There is a condition of septic poisoning occasionally met with, resulting from the introduction into the system of septic malaria through the drinking water, which so closely resembles that which is the result of typhoid poisoning, that it is almost impossible to make a differential diagnosis. In these cases the absence of the rose-colored spots is almost the only distinguishing feature.

Pneumonia.—Pneumonia, with typhoid symptoms, is sometimes mistaken for typhoid fever; it is called in your books *typhoid pneumonia*. The differential diagnosis is not difficult if you remember that the pneumonia which complicates typhoid fever does not come on until late in the fever, and you have the regular history of typhoid fever preceding its development. On the other hand, when the typhoid symptoms are present from the beginning of, or come on at the end of the second stage of the pneumonia, the physical signs of the pneumonia will attend or precede the typhoid symptoms. There will be cough and the characteristic pneumonic expectoration; there will be no eruption and no typical variation in temperature.

If you do not see a patient over sixty years of age with this type of pneumonia until the second or third week of its progress although evidences of lung consolidation may be present frequently, it will be very difficult to decide whether the pneumonia is or is not complicating a typhoid fever, and under these circumstances of course the differential diagnosis will be very difficult.

Gastro-enteritis.—In the adult this disease is quite readily distinguished from typhoid fever, as the diarrhœa and vomiting precede the febrile movement; the fever is irregular in its development and progress, and the temperature rarely rises higher than 103° F. In a child between two and six years of age, it is very difficult to distinguish gastro-enteritis, or infantile catarrh, as it is sometimes called, from typhoid fever. The eruption is not so prominent or constant a symptom in the child as in the adult, and with both diseases we have diarrhœa, tympanitis, and typhoid symptoms. These circumstances render many cases of this character difficult of diagnosis. When the entire symptoms precede the fever, and you can have a history of the case, and a thermometrical record from the beginning of the fever, in most cases you can readily make the diagnosis; but if you do not see the case until it has reached the second week of its progress, and you have no accurate or reliable history of its development, a positive diagnosis is impossible.

Trichinous Disease.—Poisoning by trichinæ has frequently been mistaken for typhoid fever. This condition is not unfrequently attended by diarrhœa, vomiting, and the development of other typhoid symptoms; but with poisoning by trichinæ there is almost constantly present muscular pains and œdema

of the eyelids, which will be sufficient to arrest your attention. We have then in poisoning by trichinæ, diarrhœa, vomiting, tympanitis, rapid emaciation, great exhaustion, a brown, dry tongue, high temperature, and other typhoid symptoms; with these you have the œdema of the face, especially of the eyelids, and the most intense muscular pains. By removing a small portion of the muscular tissue and placing it under the microscope, the trichinæ can be seen, and thus you will be enabled to make a positive diagnosis.

POLYPI AND HYPERTROPHY OF NOSE.

REMOVAL OF POLYPI AND REDUCTION OF SIZE OF NOSE.

By FRANK H. HAMILTON, M.D.,

NEW YORK.

W. G., an Irish girl, about 25 years old, consulted me in Jan., 1876. She said the nose had been filling up and becoming deformed ever since she was a child. Her health was never perfect. On careful examination, both nares were found to be filled with soft polypi resting upon, or originating from a more solid mass, which proved subsequently to be sarcomatous. The gradual development of the polypi had resulted in a remarkable expansion and hypertrophy of the nose. The nose was lifted in the centre;

and upon each side the nasal processes of the superior maxillæ formed large arches, springing apparently almost from the malar bones. The nasal processes were also much increased in breadth, in the direction of, from above, downwards. The orifices of the nares were expanded, and her whole appearance was such that she was unable to obtain employment. The accompanying wood-cut, copied from a photograph taken by the Bellevue Hospital photographer, Mr. —— Mason, gives a faithful representation of her appearance at that date.

Operation, Jan. 13, 1876, before the class of medical students at Bellevue Hospital. The patient being under the influence of ether, and to prevent the blood from entering the larynx, the posterior nares were carefully plugged with tents of sheet lint, to which were attached strings; the strings being brought out of the mouth and committed to an assistant. These strings were designed to facilitate and control the removal of the tents. The polypi were then rapidly removed by evulsion; strong forceps being employed for this purpose. When all had been accomplished which could be, in this direction, and the very profuse hemorrhage had abated, the plugs were removed from the posterior nares; and, with the face of the patient hanging downwards from the side of the table, what remained of the polypi was removed by my forefinger thrust forwards from the posterior nares, and with curved forceps introduced into both the posterior and anterior nares.

Having completed the removal of the polypi, I proceeded to reduce the size of the nose; which was done in the following manner. An incision was made along the anterior margin of the nasal process of the left superior maxilla, extending from the ridge of the nose to the cheek; from each extremity of this incision the knife was carried upwards about one inch; the quadrilateral flap thus laid out, was lifted and the entire nasal process exposed. With the handle of the knife the under surface of the bone was separated from its periosteum; and this was effected with great ease, the attachment of the periosteum to the bone appearing to be very slight. With a bone-cutter the nasal process was then severed at each extremity and removed. In the same manner the hypertrophied process of the right side was removed also. The flaps were returned to their places and the wound closed by delicate silk sutures. Neither of these incisions exposed or penetrated the nasal cavities.

The wounds healed kindly, and the nose soon assumed its present appearance. It is straight and comely, only that it is a little too broad upon its dorsum, owing to the fact that the ossa nasi are rather wide.

The accompanying wood-cut is from a photograph taken a few months after the operation was made.

Nine months after the operation, the polypi had not returned.

The Metrical System has been adopted in Austria, and druggists are required by the Government to conform to it in future.

CEREBRAL EXHAUSTION,

WITH SPECIAL REFERENCE TO ITS GALVANO-BALNEOLOGICAL TREATMENT.

BY GEORGE M. SCHWEIG, M.D.

(Read before the "Medical Journal Association," Oct. 20, 1876.)

Neurasthenia, or "nervous exhaustion," is a very comprehensive term, which may apply to the cerebral, spinal or sympathetic nervous system, or to any or all of these combined. Indeed, although referable primarily to one or other of them, the affection rarely advances far without one or both of the sister-systems becoming involved—a very natural sequence, when we consider their close relations, anatomically as well as physiologically.

I propose in the present paper to limit myself to the form that involves primarily the brain, and which may aptly be termed *cerebral neurasthenia*, or *exhaustion*.

Let us glance briefly at the etiology, pathology and symptomatology of this affection, and we will then be prepared to proceed more intelligently to the discussion of a rational treatment.

Of *causes*, we have the predisposing and the direct. The *chief* predisposing cause may be sought in a mind that lacks stamina, or staying power. As a feeble muscle succumbs readily to continued trying activity, a thus feeble mind, be it otherwise never so clear, or even brilliant, will yield prematurely to long-continued deep thought or hard study. The inherited *neuropathic diathesis* is no doubt an important factor in the genesis of the disease. As may be readily inferred from the nature of their avocations, physicians, lawyers, inventors, etc., furnish proportionately the largest contingent to this class of patients. So far as my own observations go, the disease occurs almost exclusively in the middle-aged, the young and the old being comparatively exempt.

A word in regard to the influence of *sex*. Although occurring almost exclusively in the male, I do not believe that therefore the female is less predisposed to this affection. It seems to me, on the contrary, that this disproportion is owing alone to the circumstance that, in the present order of things throughout the civilized world, man does the hard brain-work, the proportion of females who devote themselves to the learned professions or other pursuits requiring mental exertion, being too inconsiderable to deserve more than passing mention. This, I admit, is of late becoming less so than it formerly was; but I contend also, that when women shall come to furnish a numerically respectable quota to the professions that demand intellectual work, they will then also furnish their proportion, or more than this, of cases of cerebral exhaustion.

The main direct cause of cerebral neurasthenia is simply "abuse of the mental faculties." As is the case with many other organs, the mind can be overfatigued, again and again, until finally prostration, more or less complete and permanent, supervenes. In quite a number of instances, however, we have a *supplementary* cause in collateral influences on the mind, in the shape of depressing emotions and thoughts resulting from family or business troubles, sickness, etc., that render this organ less competent to bear up under taxations that, under ordinary circumstances, it might have sustained with impunity.

With respect to *pathology*, little is to be said. We know that primarily the disease is merely functional; observation, however, teaches that it is frequently the predecessor of so-called "idiopathic cerebral softening." Whether in such instances the cerebral neurasthenia is merely the initiatory symptom of the softening, or the cause of this, is for the present an open question. Theoretically, we may assume that in cerebral exhaustion a foundation for organic changes has been laid by the repeated hyperæmiæ superinduced by the increased afflux of blood which, physiology teaches us, must have accompanied each separate mental strain. In a considerable proportion of the cases, these passing active hyperæmiæ lead to a permanent and more or less intense passive hyperæmia, due directly to oft-repeated over-dilatation of the capillaries.

The absence in cerebral exhaustion of any uniform anatomical change or lesion, compels us to cast our eyes in another direction. Of all theories as to the pathology, none appears to me more likely or reasonable than that of *nutritive changes;* indeed, I can think of no other. The nature of these changes is matter for the future histologist.

Before leaving the subject of pathology, it appears to me appropriate to cite a few words from Professor Erb,* treating of a kindred subject—"Spinal Neurasthenia." Speaking of the nature of that affection, he says: "It appears most natural that we have to do here with *subtile nutritive changes* in the spinal cord, which we are compelled for the present to assume in so many diseases of the nervous system. . . . We possess as yet no knowledge whatever in regard to the nature of the nutritive changes that take place here. . . . The theory that appears to me more reasonable than any other, is that we have to do with an enhancement and fixation of the physiological "fatigue" of the nerve elements, that always follows severe and protracted irritation. In such pathological cases, then, we have only to suppose that this fatigue is not compensated rapidly and promptly, as is the rule under physiological conditions."

The *symptoms* that may follow in the train of cerebral exhaustion are so manifold and varied, that to treat of them in detail would be entirely beyond the limits of the present paper. I shall therefore confine myself to the more prominent and constant of them.

As a rule, the first symptom noticed by the patient is a disinclination for mental labor. If this feeling be for the time overcome, and an attempt made to perform brain work, a comparatively brief application will suffice to exhaust the power of thought, and bring on confusion of ideas. The mind has lost its staying-power. In some cases the memory is enfeebled, in others it remains quite unaffected. To these purely mental symptoms, certain physical ones are soon superadded.

Agrypnia is a very common concomitant from the beginning. Of regional morbid phenomena, those within the sphere of the pneumogastric nerve take precedence, both as to priority and importance, over all others. Among them may be classed: Disturbances of the heart's action, the functions of the stomach, liver, intestinal canal, etc. Vasomotor disturbances are common. Cerebral nerves other than the pneumogastric may in turn become involved. Thus we often have here neuralgiæ of varied form and intensity. At first located in some of the cranial nervous ramifications, these appear frequently within the sphere of the sympathetic and spinal nervous

* Ziemssen, Hand-Book of Special Pathology and Therapeutics; Vo XI., Part II., p. 878.

systems, and may then be classed as secondary phenomena.

I have never observed paralysis, although one patient told me that in the beginning of his trouble, which was some six years before I saw him, he had several attacks of hemiplegia without loss of consciousness, from which he made a spontaneous recovery in less than twenty-four hours. At a later period he had another attack, this time accompanied by loss of consciousness. Paretic conditions, on the other hand, are the rule, although they rarely make their appearance until the disease has existed for some time.

Judging from symptoms pointing in that direction —such as vasomotor disturbances, regional pareses, neuralgiæ or paræsthesiæ, there can be no doubt that both the sympathetic system and spinal cord—especially its upper portion, become functionally involved after a shorter or longer period. From a local cerebral disturbance, if not checked in time, we thus see developed, more or less speedily, a general neurasthenia, with a tendency to organic and perhaps fatal lesions.

This mere glance at the nature and manifestations of cerebral exhaustion and its *sequelæ* is yet, I believe, sufficient to render apparent the necessity of instant and energetic treatment *as early as possible*, when we have still to contend with the primary condition alone. In addition to their aim to relieve the morbid condition itself, our therapeutic efforts become at this time even more important as a prophylactic against organic and perhaps incurable *sequelæ*.

The *diagnosis* of cerebral exhaustion in its first stage should present little difficulty; yet it is precisely here, where its recognition is of most importance, that mistakes in diagnosis most frequently occur. Where the trouble is looked upon as cerebral, the absence of unilateral symptoms, such as hemiparesis or hemiplegia, and other characteristic signs of special organic cerebral lesions will usually suffice to stamp the trouble as functional, and, in conjunction with a just appreciation of the anamnesis and phenomena presented, lead to a recognition of its true nature.

It is not, however, in this direction that diagnostic errors are most frequent. Of the instances of mistaken diagnosis that have come under my notice, nearly all were in the direction of the abdominal viscera. The symptoms due to functional disturbance of the pneumogastric were looked upon as primary conditions. The stomach was often accused, but that scapegoat *par excellence*, the liver, was generally held responsible for everything. The golden opportunity for a rapid and decisive therapy was thus often irretrievably lost, entailing much and prolonged suffering, that might have been obviated by a prompt, correct diagnosis and rational treatment.

In the more advanced stages, even where the neurasthenia has become general, or organic disease developed, the history of the case will, if minutely investigated, almost always throw light on the origin and primordial nature of the trouble.

The *prognosis* depends not only on the severity of the case, the duration of the cause and the hereditary disposition of the patient with respect to nervous disease, but also, and perhaps chiefly, on the patient's ability to lay aside all other considerations, and follow out strictly the course laid out for him by his medical attendant. Where this can be done unqualifiedly, a favorable prognosis is the rule.

We may now proceed to a consideration of the *treatment* of cerebral exhaustion. The one great object of a therapeutic course is patent; it is to seek, by *appropriate* tonization and physiological stimulation, in conjunction with the much-needed rest, to restore to the brain its lost vigor; to correct its impaired nutrition; in short, to bring it back to a normal state.

To effect this, it is of the utmost importance that no time should be wasted with tonic measures that exercise but little if any *immediate* influence on the brain. In view of the important share that prophylaxis bears in the indications for treatment, great circumspection is requisite in order to choose such remedies as are best calculated to insure *speedy* results. I will now proceed to describe the treatment which of all others has rendered me the best services.

The very first condition for treatment, the *sine qua non*, is "rest for the exhausted brain;" not a brief rest of days, nor even weeks, but absolute abstinence from all mental tasks throughout the entire treatment, and until health is perfectly restored. Unless this can be absolutely complied with, other measures are useless, or nearly so. It will be well if at the same time all disagreeable emotions, cares, or harassing thoughts of any kind can be avoided. This, I know, is not always possible, but should be carried out as fully as circumstances will allow.

Of remedial agents, I have found galvanism to surpass in efficiency all others. At a first glance, it would seem as though the objects to be attained by this could be best realized through *direct* galvanization of the brain. This, however, is impracticable. A direct current of sufficient intensity to influence the brain, would prove injurious on the principle that enfeebled organs will not bear *strong* stimulation. Moreover, we cannot with the utmost care prevent the occurrence at times, during galvanization of the brain, of giddiness, ocular flashes, faintness, etc.—all undesirable phenomena, to be avoided in the electrical treatment of functional enfeeblement of the brain. If, on the other hand, we employ a current so feeble that occurrences such as those enumerated become impossible, or at least very remote, and that *strong* stimulation is out of the question, it becomes very questionable, to say the least, whether a current reaches the brain at all; and if yes, it will be too insignificant to accomplish any therapeutic results. My own experience, then, with galvanization of the brain, has long since led me to abandon it in the initial treatment of cases of enfeeblement of that organ.

The manner in which I here seek to affect the brain is by *general* galvanization, administered in its *only perfect form*—the GALVANIC BATH. By its means the brain is made to sustain a reflex or indirect influence from *all* points of the periphery, and at the same time, through derived currents, a mild direct impression, which can be regulated at will, not only by modifying the intensity of the current, but also by establishing more or less perfect communication between the occiput and the water of the bath. This direct influence differs from ordinary cerebral galvanization, whether bipolar or unipolar, in that here no electrode is applied directly to the cranium, which during the entire process is never for a moment in a direct line between the two poles of the battery. It is *never* attended with any of the undesirable phenomena enumerated above as not always avoidable in local galvanization. There are, indeed, no subjective sensations during the bath to indicate that the brain is being acted on at all. Nevertheless, an interruption or reversal of the current will promptly produce the galvanic taste, and, if the current has sufficient tension, ocular flashes, etc., thus establishing beyond doubt the fact that the cranial nerves, *resp.* the brain, participate fully in the gal-

vanic influence. The galvanic bath, then, of appropriate intensity for each individual case and stage, I look upon as the most valuable of all remedies we possess for the treatment of cerebral exhaustion. Bringing, at one and the same time, a suitably modified unipolar direct current and a reflex stimulus from every point of the periphery to bear on the brain, it stands unique among electro-therapeutic procedures. It not only furnishes to the brain tone and the much-needed physiological stimulation that tend to enhance its nutrition, but, through its invigorating influence on this organ, allays the irritability that is so frequent a concomitant of debility, and thus becomes a sedative, and most efficient hypnotic. Its stimulating influence on the vasomotor system, together with its counter-irritant action on the skin, render the galvanic bath a very superior, if not the best equalizer of the circulation that we possess, causing it thus to exercise a further beneficial influence on the suffering brain by unloading its surcharged bloodvessels. In addition to these *direct therapeutic* effects of the galvano-electric bath, this becomes, where the faradic current is added, a means for symptomatic and also prophylactic treatment, more universally applicable and useful than any other single remedy. Of its hypnotic properties, as well as its influence on the circulation, I have already spoken, and in both these respects it does all that can be expected or desired for any agrypnia or vasomotor disturbances that may be present. The well-known anti-neuralgic properties of the galvanic current render it also an efficient corrective for any intercurrent neuralgiæ. The circumstance that in the bath no organ in the body is exempt from the electric influence, is of great importance in the treatment of functional disturbances of the important organs that are innervated by the pneumogastric and sympathetic nerves. Thus, dyspeptic symptoms, hepatic torpor, irregular cardiac action, morbid modifications of the alvine process, etc., are as a rule rapidly ameliorated.

Thus far I have considered the effects of the galvanic current alone. The faradic current, however, may likewise be employed with great advantage, chiefly in the treatment and for the prophylaxis of paretic conditions. Passive muscular contractions of any group or groups of muscles can be obtained in the faradic bath with great nicety, both as to locality and energy of contraction. The importance of this will be readily conceded. Nor is its influence on paresis the sole benefit to be derived from the faradic current. By the very muscular contractions thus evoked, capillary stases are relieved, and a mighty auxiliary is thus furnished the galvanic current in its effects on the circulation.

On the whole, then, the electric bath meets all the indications of the disease but one, viz.: special nourishment for the brain. In addition to an appropriate diet, this may be best supplied by the exhibition of either phosphorus or cod-liver oil, or both, according to indications in individual cases. The phosphorus may be given pure (in pill or solution) or as phosphide of zinc. Where electricity is employed, I consider medicinal stimulants superfluous; nor, with one exception, do I know of any other remedial agents, in addition to those enumerated, from which special benefit might be expected. The exception I allude to is the bromides. These may be advantageously given in cases that are characterized by irritability so intense or cerebral hyperæmia so decided as to indicate the employment of some additional remedy to combat these special conditions.

As for further symptomatic treatment other than that furnished by the electric bath, such may become necessary, and must be determined as occasion arises, according to the best judgment of the practitioner.

A few words as to the mode of administration of the baths in the treatment of cerebral neurasthenia. It is impossible in this respect to lay down any routine formula, either in regard to the duration of the bath, the temperature of the water, or the intensity or direction of the current. Each case has its own laws. A few general suggestions may nevertheless be not out of place.

Very mild currents should be employed in the beginning. As recuperation advances, stronger currents may be gradually introduced. The intensity of the currents should be carefully regulated to keep pace with the gradually increasing capacity of the various organs to respond to the electric stimulus without detriment. Bath currents may be used from the first, although the faradic current is strictly necessary only where paretic or sub-paralytic conditions exist. The galvanic should precede the faradic current, and be employed for not more than ten minutes. Where irritability is a feature of the case, the current should be descending—otherwise ascending. This may be followed by the faradic current, not of sufficient intensity for the first few baths, however, to cause any but *slight* muscular contractions. In most of the cases iron may be advantageously added to the bath. The duration of the baths should at first not exceed fifteen minutes; in some cases this even is too long, the patient complaining of being fatigued perhaps after the lapse of ten minutes. Where this is the case, the bath should be at once terminated. It is, in these cases, not the electric current, but the warm-water bath, that gives rise to the sense of fatigue. Later on in the treatment, the duration of the baths may be from twenty to twenty-five minutes, according to indications.

The practitioner who is familiar with the physiological and therapeutic effects of electricity, will readily grasp the requirements of individual cases; while he who has not given attention to the subject, will either have to abandon the method, or relegate its application to some colleague who possesses the necessary information.

The clinical tableau presented by cerebral exhaustion is so variable, that to introduce here a clinical record of one or two cases only would serve no purpose. As my limits therefore do not admit of the introduction of a sufficient number of cases, I must for the present refrain from a clinical consideration of the subject.

NEW YORK, 160 Second Avenue.

Progress of Medical Science.

A SUBSTITUTE FOR THE COLD BATH IN THE TREATMENT OF FEVERS.—Despite the great success of the treatment of typhoid and other fevers by the cold bath, the possibility of a dangerous nervous shock during its employment, and the difficulty of obtaining the necessary assistants, have hitherto prevented its general adoption in private practice, Dr. Dubois of California now proposes as a substitute for the bath, the running water-bed, which is based on the theory that swiftly running water, or rapidly moving air at the temperature of the body in health will more safely remove excess of heat than still water at a temperature from 20° to 30° below it. A wire-woven mattress is fitted

on a three-quarter camp bedstead, and underneath it, at a distance of a few inches, is hung a shallow tank of rubber, the bottom of which is interrupted in such a way that water let in by a tube at the head of the bed will be forced to zigzag down to the foot, where it will be carried off by another tube. The tank is covered by two closely fitting covers pierced with holes, so that by sliding one over the other, the holes can be closed to any desired extent. The whole arrangement, bedstead and all, can be taken apart and folded up into a bundle six or eight inches in diameter, by three or four feet in length. The best covering for the wire mattress is felt pierced with holes, or a thin hair or wool mattress. When this bed is not obtainable, a few iron tubes connected by rubber tubing, or even a garden hose run up and down a few times under an ordinary bed, would answer on an emergency. These could be connected at one end with a water tank, or faucet, and the waste water conducted to a convenient place from the other end.

The Use of Aromatic Sulphuric Acid in Necrosis.—The Boston *Medical and Surgical Journal*, for August 17th, contains the history of a case of necrosis of the alveolar process, that was cured by daily injection of aromatic sulphuric acid in the proportion of a drachm to the ounce of water, into the substance of the spongy swelling that surrounded the diseased bone. The teeth were very loose, and the case was one that apparently called for operation; but under the above treatment, combined with the use of tonics and an animal diet, the teeth gradually tightened, and in a year the cure was complete.

Easy Method of Removing Adherent Mucus from the Os Uteri.—Prof. Pajot recommends the following as the easiest method of removing the viscid, tenacious mucus, characteristic of certain forms of catarrh, from the uterine orifice. Dip a ball of charpie into the yolk of a fresh, raw egg, apply it for a few seconds to the mucus, and then inject one or two syringefuls of water into the speculum, continuing meanwhile to apply the charpie gently to the cervix. Now let the water flow out, and dry the cervix, when it will be found to be completely cleansed of all secretion.

Homicide by Negligence.—In February last a workman in Algeria, wanting to get a purgative dose of rhubarb, went to a druggist, who gave him instead a large dose of hellebore. A few moments after taking the drug the patient felt very ill, and he died three hours afterwards. The autopsy showed the presence of the intestinal lesions that are excited by hellebore. The druggist insisted that hellebore had been asked for. In consideration of the facts that he did not warn the purchaser of the dangerous character of the drug, and did not place on the packet the double label, red, orange, and black, which indicates that the contained substance is for external use, the court at Nîmes confirmed a previous judgment, by which he was condemned to one month's imprisonment and a fine of 200 francs, for homicide by negligence.

A Simple Method of Treating Umbilical Hernias in Infants.—M. Archambault has for some time past employed with gratifying success the following plan in the treatment of the umbilical hernias of infants. A piece of white wax is softened, and fashioned with the fingers into a ball, which is then cut in two, so as to form two hemispheres. One of these hemispheres, which must be of a size proportionate to the umbilical ring, is applied to it in such a way that its spherical surface securely fills the opening, and is then retained in position by a strip of plaster. Instead of wax we may use gutta-percha, previously softened in warm water. Both of these substances, about two hours after their application, become sufficiently softened to adhere to the skin. If the plaster excite cutaneous erythema, it should be removed every two days, and the skin powdered with rice-powder.—*Le Bordeaux Médical*, September 12th.

Coloration of Wine by Fuchsine.—M. Ritter, of Nancy, recently undertook some experiments on the adulteration of wine with this substance, the results of which must be interesting to wine drinkers. He presented to the *Société Médicale de Nancy* specimens of the different coloring-matters used in the manufacture of adulterated wine, all of which have fuchsine for their base; two cubic centimetres of any of them were sufficient to give a strongly vinous tinge to a quart of fluid. Some of these coloring-matters are strongly arsenical, others are less so, while some contain hardly any arsenic. A man who drank for six days wine colored with arsenical fuchsine, continued for two days afterwards to pass urine which contained arsenic. The importance of this fact, from a medico-legal point of view, will be evident to all. Fuchsine is added to inferior or partially spoiled wines in order to give them the appearance of a superior article; also, to wines to which a large amount of alcohol, and a third, or even half of their volume of water have been added; finally, to wines that have been simply diluted with water, the fuchsine in the last two cases being added principally to mask the presence of water. By M. Ritter's process the presence of fuchsine in the proportion of 1 to 30,060 can be discovered.—*La Tribune Médicale*, September 3d.

Some of the Causes of Goitre.—At the séance of the *Association Française pour l'avancement des Sciences*, on August 23d, M. Nivet, of Clermont, read a paper on this subject, in which he held that medical writers have hitherto laid too much stress on geological influences in the pathogeny of endemic goitre. Magnesian rocks, with or without pyrites, are not by any means constantly found in countries where bronchocele is common. He thinks that, in the department of Puy de Dome, the great atmospheric currents coming from the mountains on the west have an appreciable influence in the etiology of this disease. These currents, however, are but one among many other causative influences. The use of magnesian waters, and living on magnesian soil, create a predisposition, perhaps; as do also bad nourishment, overcrowding, excessive work in the glare of the sun and on land exposed to the west winds, and the ingestion of large quantities of cold water (a cause which has been recognized by many observers). Goitre, beginning as an acute disease under these conditions, attacking for instance immigrants, who, with their families, had been previously free from it, may become chronic and constitutional, and susceptible of hereditary transmission; "and thus acute goitre becomes the nursery of epidemic goitre." Acute bronchocele has been said to consist in a rheumatic affection of the vaso-motor nervous system of the thyroid gland.—*Gazette Hebdom. de Méd. et de Chir.*, September 1st.

Parotiditis.—The inhabitants of the Scilly Isles have been suffering for the past six weeks from an epidemic of mumps. Most of the children have had the disease, and it now attacks the adults. The usual complications are quite prevalent.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, November 4, 1876.

PROFESSIONAL RIGHTS IN THE NAVY.

THE peculiar position of the medical officer of the navy has often been a subject for comment. Although an educated professional gentleman, he is always made to feel himself far below the line officers of his own relative grade. The latter, by usage and regulation, have a certain divine right of rank and privilege, which evidently must not be questioned. A great many arguments have been offered to prove why this should be so, and as the most of them have been founded on technical interpretations of "naval discipline" and "respect to superiors," conclusions were easily reached. Under the circumstances it was hardly possible to suppose that these conclusions were in favor of elevating the ship surgeon either in rank or authority. But the question of naval staff rank has been so fully discussed in these columns that we shall not refer to it in detail. The upshot of the whole struggle for increased rank has practically resulted in an understanding on the part of the officers of the line, that the medical officer has no rights which they are bound to respect.

The surgeons asked for rank for the sole purposes of allowing them the requisite authority to give orders in their own department and to enable them to claim a compensation to which their professional services were entitled.

Every one interested in the question knows what has been the result of the controversy. In the cold comfort of a virtual defeat he was content to fall back upon his professional rights and bury his mortification in the rounds of strictly professional duty. This was the last resource, it is true; but being considered safe from the impertinence of the authority of the line, it was the best that offered. It seems, however, that naval discipline has reached him even there, and that he must resign to his superiors the right of expressing a professional opinion.

It may be within the recollection of some of our readers that a surgeon of the navy was court-martialed and reprimanded for not taking a man from the sick list because he was commanded to do so by a superior officer of the line. It was in vain for the surgeon to give his opinion that the man was unfit for duty, as what is technically called naval discipline must be maintained. The Secretary of the Navy, with an attempt to show a charity to the poor offender, on account of previous good character, publicly declared that "the disobedience complained of in this case was the result of a mistake of judgment in regard to professional rights and duties, rather than of a deliberate intention of wrong" (vid. MED. RECORD, vol. iv., p. 373). His explanation of the reasons of the sentence was only excusable on the score of its ignorance and stupidity. This did not, however, alter its significance as an authoritative precedent for similar cases.

Knowing the facts connected with this case we are not surprised to learn that another surgeon was found guilty of violating naval discipline because he gave it as his professional opinion that the ship, of which he had medical charge, was kept in such a damp condition by a constant wetting of the decks that the convalescence of several cases which he had on board was thereby retarded. The sentence of the court-martial was a public reprimand, and the "laws governing the navy" received an intelligent and noble vindication.

The foregoing remarks may serve to introduce a consideration of the latest case of violation of naval discipline by the unfortunate ship surgeon. The fleet surgeon of the Asiatic squadron, Dr. Turner, soon after joining the flag-ship Tennessee, made several reports to the admiral concerning the bad hygienic condition of the vessel. This impertinence of the surgeon called down upon him the wrath of the admiral, captain, and executive officers, which resulted in a peremptory order that he should cease making hygrometric and other scientific observations. Remonstrance was in vain, and Dr. Turner finally appeals to the Secretary of the Navy for the abrogation of the order. The only encouraging element in this miserable and disgraceful intolerance of professional rights is the manly and spirited protest of Surgeon Turner. It is well that his brethren of the medical staff of the navy have such a valiant champion, and that the profession at large have such a dignified and efficient spokesman. He defines his situation as a medical man so well that we gladly quote the greater portion of his letter:

"The order forbids me to pursue a scientific medical investigation, for it was to determine some of the physical elements under which men, especially seamen, live, that I commenced this study. The examination of such elements is a part of physiology, and more particularly of etiology. This, Mr. Secretary, is my right—the right of my profession. It is axiomatic; does not permit of discussion, because self-evident. It has never been abridged or curtailed. Here and everywhere, from ages past to the present time, the

duty to search for the causes affecting the health and lives of men has been the inviolable right of the physician. The order also suspends the right to the use of my senses. These are beyond military law, and, as I have stated, are my birth-right, inalienable, and not limited by my duties or obligations as a naval medical officer. I again refer to the invasion and arrest of my rights, privileges, and immunities as a citizen. The law of the land guarantees me protection in the peaceful pursuit of my occupation. In this pursuit I have not interfered with the discipline of the service, nor the laws governing the navy. The right to use my private judgment upon all well-decided and scientific facts is ignored. To observe and to experiment, I need not inform you, Mr. Secretary, are the only sources of knowledge and the foundation of science. The right to do so is the endowment of nature to every human being. The order arrests this right."

The appeal has just reached Washington, and is before the Secretary of the Navy. What his decision may be in the light of precedents which he has already established, it is difficult to say. If he had never insulted the profession before through its representatives in the medical staff of the navy, it would be a reflection upon his common sense to doubt for a moment the course he will take.

WATER SUPPLY OF NEW YORK.

The scarcity of water supply in New York has been a subject of very serious complaint. The severe drought of the past summer, and the consequent low level of our reservoirs, continues its effects to such an extent that the Aqueduct Department has been compelled to lower the pressure to one-half during the day, thus cutting off the supply to all but the lower floors of the dwellings. Although New York has been congratulating itself upon its ample reserve against necessities, the fact stares us in the face that we are, in any unusual emergency, apt to overdraw our account. Our city fathers have even been roused from their wonted apathy to the extent of a concern for the future, and have deliberately proposed some improvement upon the present system. The suggestions for extra dams are reasonable enough, except for the small items of time and expense required in their construction; more favor, however, is shown to the expediency of laying extra and independent mains, with independent sources of supply. But, in any event, time and money will be required to effect an improvement. In the meantime, trusting to the chances of copious autumnal rains, the only prospects for the near future suggest the most rigid economy of the Croton.

The present trouble has originated in a great measure from the wilful waste of water by many tenants, and suggests the necessity of some prevention of this waste without causing economical consumers to suffer. The difficulties in this direction are very great. Practically, they have been found to be so far insurmountable as to compel our water authorities to resort to extreme measures.

It is useless to appeal to the good sense of the people at large, so long as the ignorant and unthinking are left free to the dictates of their individual judgment. There should be some means of punishing the actual waste of water by an extra tax. Under the present system this is impossible, as the rate is by no means regulated by the actual amount of water that may be used. The only way to remedy this is to regulate the supply by meter, thus making each consumer pecuniarily responsible. This has been tried with good effect in other cities, and while it does not check the use of water for any useful purpose, it certainly prevents a wilful waste. We may be compelled to adopt this system in the end before we can see our way out of our present trouble. In fact, at present it is the only one which seems to offer any hope.

For the time being, this sudden curtailment of supply threatens to be more than a mere inconvenience. When the water pressure is diminished, some of the water-closets in the upper stories cannot be used, or if used at all, in order to keep the traps full, water has to be carried to them from other parts of the house. It is unnecessary to mention the liability of neglecting these precautions to the escape of sewer gas into the dwellings "even of the best regulated families." The same remarks apply to the traps under the wash-basins. Not long since it was deemed necessary, in view of the danger of dry traps, for the health authorities to officially warn the public against their tolerance. Again, the sewers deprived of the accustomed amount of flushing became the receptacles of stagnant filth, the poisonous fumes of which have been obtrusively manifest at the mouths of the culverts. Is it not time, then, that the authorities should bestow themselves to the full appreciation of the necessities of the hour, and by some rational and prompt remedy not only ward off present evils, but effectually prevent others which may come.

The best we can hope for the present state of affairs is that, by the natural replenishment of our reservoirs, the trouble may not last long; but the liability of similar occurrences in future lends to the whole subject of water supply a seriousness of consideration which has never presented itself before.

The Profession and the Newspapers.—The London *Lancet* is glad to notice the action recently taken by the Kings County (N. Y.) Medical Society in reference to medical advertising, and says: "This is highly creditable to the profession on the other side, and affords an example which might be copied with advantage."

Introductories.—The London medical schools are contemplating the abolishment of introductories, their place being taken by a professional *conversazione*.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 5, 1876.

Dr. S. S. Purple, President, in the Chair.

The Academy acknowledged the reception of donations to the library from Drs. Barker, Bell, and Buck, and from the College of Physicians at Philadelphia. Among Dr. Barker's presentations was a valuable work, printed in the year 1550. A resolution authorizing the employment of an assistant librarian gave rise to considerable discussion, but was finally adopted.

THE MALADY OF INNUTRITION.

Dr. George Bayles read a paper upon the above subject, in which he directed attention chiefly to the comparative newness of this elemental cause of suffering on this continent. Poverty was attended by an insufficient food supply, and the present deprivation and suffering was due to the lessening of the streams of pecuniary resources. It was estimated that fifty per centum of the population had suffered pecuniary losses within the last three years, and that at present there were ten per centum who were deprived sufficiently to reduce them to a level with the common herd. The result of such deprivation was believed to be physical degeneracy, and in the wake of that, disease and suffering followed as an inheritance. In the author's experience diphtheria had been largely dependent upon improper food supply; hence food became medicine and proper medicine food in the treatment of such cases. It was his opinion that children at the breast were just as liable as any other class to diphtheria, if they had an improper supply of food, and what was true of diphtheria was believed to be true of many other diseases where blood deterioration was present. Tuberculosis prevailed; nervous disorders were on the increase; uterine irregularities were multiplying; cachexias and eczemas were more and more numerous; acute diseases did not seem to lag, and pneumonia had been excessively prevalent; ephemeral fevers and those of the rheumatic order had also been upon the increase, etc., etc. It was thought hardly just to attribute to lack of proper diet the marked increase in all these diseases, both chronic and acute, but as a positive condition preparing the way its part had been equal in importance, if not greater, than all others. The malady of innutrition, if not suppressed, would prove fatal to all the future. Chronic hunger would jeopardize long life. Those disastrous consequences were to be averted by turning to our advantage the laws of heredity, by establishing upon a firm basis the habits and consonant laws relating to longevity, and by working out a system of communal contentment satisfactory to all, meaning thereby a submission to decently good states and conditions of society. Improper food, irregularly taken and badly digested, was believed to be one of the crying evils of the wealthy classes, and in their case it became a malady and produced correspondingly disastrous effects. The doctor referred to the diet of our boarding-schools, and noted the failure on the part of the scholars to get what was necessary to properly nourish and sustain the body at that period of life.

It was thought that constitutional mischief might follow the observation of Lent as insisted upon in the Romish Church. The malady of innutrition was regarded as an induced condition, therefore a preventable dyscrasia. It was to be prevented by giving to the citizen full knowledge of its evil influence; by establishing numerous centres of food supply, free to all who were in need; by giving a hearty and liberal support to all culinary charities; by the enactment of laws favorable to communal contentment, upon a right basis and in accordance with a right interpretation of the principles which that political condition implied.

Dr. Gouverneur M. Smith observed that perhaps the author of the paper had laid too much stress upon the mere article of food as a cause of innutrition and consequent cause of disease. Certainly we had a most abundant supply of food here. It was improperly prepared without doubt, and in that way might be a cause of disease both in the country and city. But perhaps there were other causes of disease, such as relate to disturbances of the digestive organs, produced by occupation and habits of life, so that the best of food, and served in the best possible manner, could not be properly digested. Others might give way to the demands of fashion to such an extent that the best food, and taken from the best prepared table, could not be appropriated. There were many allied causes which depressed the nervous system and interfered with proper digestion, such as intemperance, etc., etc. It was regarded as necessary to take into account all these accessory conditions in making up a proper estimate of the causes of innutrition.

Dr. E. R. Peaslee remarked with regard to the general proposition, that proper nutrition was of the first importance; and, in regard to food, that that should be placed first and foremost there could be no doubt. Why take food unless to nourish; and why nourish unless to form pure blood, and have that blood circulate to every part of the system, that its elements might be assimilated and form a part of every tissue and organ in the body, so as to repair the waste which had occurred? From that point of view, physiologically, food was of more importance than circulation. It was more important than respiration, for the object of respiration was simply to aerate the blood which is formed from the food. Nutrition was regarded as the question first of all in importance. It was believed to be the first link in the physiological chain—the point of departure; and if there was a failure there, failure followed everywhere as a necessary consequence. Good nutrition should be secured in spite of all obstacles, if possible, for bad nutrition hastened and secured all the malign effects of heredity. Bad nutrition made sure of the development of cancer and phthisis, if the father or mother, or both, had given the person the tendency to those diseases. It became, then, an important question for physicians to consider, for there were thousands in our land who were not able to get a sufficient quantity of food. The physician's knowledge of the evil consequences of improper nutrition should stimulate him to do and say something, in hope that the results alluded to as probable in the future might be averted. The evil influences dependent upon improper nutrition would tell upon the next generation, and that was altogether the saddest part of the picture, if the present time of deprivation was not soon passed by.

Dr. Hanks alluded to the excessively poor diet among the tenement-house population, made up, as it was in most instances, largely of bread and tea. He believed it would be well to have scattered among that class of people a printed circular containing state-

ments endorsed by the medical profession with reference to the best articles of food to be used, in order that the greatest possible amount of nutrition should be secured at the least expense. He farther did not believe that diphtheria was always due to innutrition.

Dr. Leaming alluded to his investigations, made some years ago, with reference to the influence which the so-called "swill-milk" had upon the mortality among the children in his Dispensary department. The mortality had been very great among the children, and it was supposed to be due to the consumption of that kind of food; but upon making diligent inquiry it was found that scarcely any of them had been fed upon milk at all, because the parents were too poor to afford it. The young children had been fed upon such food as the family consumed, whatever that might be. Reference was then made to the marked diminution in the rate of mortality that had been brought about in one of our public institutions for children by the regulation of the diet-list. Under seven or eight years of age the children had been given an abundance of milk and farinaceous food, with picked-up cod-fish occasionally in the summer time. No animal food at all was permitted except the milk. Between eight and fourteen, solid animal food was given three times a week; soup about twice a week, and fruit in its season. The rate of mortality was reduced from five deaths in a year to one in two years, and by subsequent modifications six years had passed with only a single death. It was the doctor's opinion that the kind of food perhaps was of more importance in sustaining proper nutrition than the quantity.

Dr. Joel Foster referred to the general prevalence of the administration of improper food to infants, and said that more good milk was required. It was one of the sayings of John Randolph that Providence had given us an abundance of good food, but that the devil had furnished the cooks.

The Academy then adjourned.

Obstetric Section.

Dr. Isaac E. Taylor, Chairman.

EPITHELIOMA OF THE CERVIX UTERI.

At a stated meeting held at the house of Dr. J. C. Peters, Oct. 16, 1876:

Dr. A. C. Post related the following case. A female patient, æt. forty-seven years, for the last seven months, and after having passed the menopause for several years, had had a recurrence of a uterine flux of blood. At first it appeared at intervals; afterwards it became continuous; the cervix uteri was enlarged and indurated, its cavity widened and occupied by a fungous growth which bled constantly, and increased hemorrhage recurred from the slightest touch. The entire fungous mass was scraped away, the underlying surface brushed over with *a strong solution of iodine (Churchill's tincture)*, and there had not been a particle of hemorrhage since. Dr. Post remarked, that plan of treatment had generally been successful in the treatment of like cases, of which there had been several in the Presbyterian Hospital.

The Chairman remarked that he had come to regard the actual cautery as the best possible means that could be employed for arresting hemorrhage in that class of cases. Scrape away the fungous material, and then brush the surface over with a cautery iron heated scarcely to a red heat—not sufficiently hot to cause any fuming of the tissue. He had used the iodine in several instances, but did not like it nearly so well as the hot iron. He had also employed the strong acetic, nitric, and chromic acids, but had set them all aside for the actual cautery, the iron being only moderately heated. If the cautery should be applied as it ordinarily was, the iron being heated to a white-heat, it would be objectionable, for the more active cauterization, as well as the use of strong acids, was liable to be followed by inflammatory action.

Dr. Mundé inquired if the disease in Dr. Post's case was supposed to be epithelioma of the cervix.

Dr. Post replied that it was so supposed, and that the disease apparently did not extend into the body of the organ.

Dr. Mundé remarked that the application of iodine to the cervix was an uncommon mode of treatment, and that in general the stronger caustics were employed. In the cavity of the uterus he had frequently used the tincture of iodine for the purpose of arresting hemorrhage, either with or without scraping, as the case might seem to demand.

Dr. Mundé inquired of Dr. Taylor regarding the certainty of reaching every portion of the surface with the iron; whether it could be so easily done as with a fluid?

Dr. Taylor replied that with a variety of form of irons every part could be easily reached. Some of the instruments he employed were very small. He further remarked that in those cases where scraping was not necessary, the tincture of iodine might be used with benefit. The disease could be certainly retarded in most cases by the use of these means. It might be necessary to repeat the cautery at the end of a week or ten days, but the hemorrhage seldom showed itself after the first application.

Dr. Joel Foster inquired whether the liquid persulphate of iron was efficient in the treatment of such cases.

The Chairman replied that it did not answer the purpose.

Dr. Mundé referred to a case in which he had scraped away the fungous growth, and then applied an alcoholic solution of bromine, one part to eight. The application was repeated in about two weeks, and no blood had been lost, it then being three and a half months since the last application. He further remarked that there was no better way to check the hemorrhage in these cases than to remove the fungous growth by scraping. The amount of hemorrhage from each procedure was not of much account. He thought that iodine was not a sufficiently strong application.

Dr. Mundé also referred to a case in which chromic acid was used, and extensive sloughing followed, probably caused by the strong acid application. Sloughing of the entire body of the uterus was produced.

Dr. J. C. Peters alluded to a case which the Chairman had seen with him, and in which iodine was used because it was thought not to demand scraping and the use of the cautery. The iodine corrected the fetor entirely, and the applications were not painful. They had been omitted for two or three months, when suddenly profuse hemorrhage made its appearance, but ceased entirely while taking dram doses of the fl. ext. of ergot every two or three hours. After that the local application of iodine was resumed, and the patient had not suffered from either pain, discharge, or hemorrhage during the last four months. The cervix uteri only was involved.

Dr. Wooster recommended the use of the curette, and to follow it with nitrate of silver (porte-caustic),

or a chromic acid solution, two grains to the ounce of water thrown into the cavity, by means of Nott's return syringe, when the body of the uterus was involved. He preferred to use the curette without the aid of a speculum. He first dilated the cervix by means of a laminaria tent, and had thrown a quart of the chromic acid solution into a uterine cavity. The action of the chromic acid was such as to close the opening of the Fallopian tubes, thus preventing any escape of the fluid into the peritoneal cavity. He was very partial to the astringent effect of chromic acid.

Dr. J. C. Peters remarked that the action of strong chromic acid was certainly peculiar as a caustic, for it produced something like a perforating ulcer; that is, its action seemed to be limited, and the inflammation that followed was not usually widespread.

Dr. Hanks remarked with reference to applications to be made to malignant growths affecting the cervix and body of the uterus, and where he did not wish to use the curette, that he had been accustomed to use the strong solution of the perchloride of iron, prepared without alcohol. Its astringent and escharotic properties rendered it much more valuable than the persulphate, and it differed from the ordinary tincture of iron in that it contained no alcohol. In cases of incipient carcinoma of the cervix or of the canal it was believed that, by carefully watching and applying this acid preparation to each little growth as it appeared, the disease could be held in check for a number of months.

DIPHTHERIA.

Dr. Joel Foster referred to several severe cases of diphtheria that had lately fallen under his care, and in which he had been called before depression of the system had become manifest. He had used locally equal parts of liq. ferri persulphatis and glycerine, applied with a camel-hair brush, and it had acted like a charm in destroying the deposit. The application caused scarcely any pain, and in his hands had proved very beneficial. The general treatment had been supporting in the highest sense of the term. When the application was made the membrane turned red almost at once, and came away, and the application was resorted to twice a day so long as the deposit continued to return. In cases where a gargle could be used, chlorate of potash was commonly employed. The doctor felt quite sure that the membrane in his cases was the genuine diphtheritic.

Dr. Hanks thought that the iron and glycerine might destroy the deposit that is found in ulcerative sore throat, but doubted whether it would destroy true leathery diphtheritic membrane. He would not call that kind of deposit diphtheritic which yielded to the local application of persulphate of iron.

Dr. J. C. Peters referred to the fact that Dr. Markoe reported a case of diphtheria in 1844, and that Dr. Sabin also reported a case in the same year. In the year 1845, Dr. Willard Parker reported three or four cases, and in the same year the doctor himself also reported a case. The disease then partly disappeared, and little or nothing was heard of it in this region until the year 1858, when Dr. A. Jacobi was the first to recognize and report its reappearance.

Dr. O'Sullivan referred to the history of a family of children through which diphtheria had passed, and all had made good recoveries under the influence of nutrition, quinine to reduce the temperature, and the local use of a saturated solution of chlorate of potash and glycerine. They began as cases of scarlet-fever, which was contracted in one of the public schools in Long Island City, only a few doors from where they lived. They were all healthy children when attacked, and the doctor believed that the result in any case depended much upon the constitution of the patient present at the beginning of the disease. The mother of those children took care of them almost constantly, was apparently a perfectly healthy woman, was pregnant, and her confinement took place within a few days after the convalescence of the last child sick with diphtheria, when she was delivered of a still born child. The question arose, what caused the death of the fœtus? Was there any relation between the death of the child and the fact that the mother had been caring for her other children, who were sick with diphtheria?

Dr. Mundé remarked that a case of congenital diphtheria had never been known, and that he was inclined to the opinion the death of the fœtus depended upon defective nutrition caused by physical and mental anxiety on the part of the mother.

Dr. O'Sullivan remarked that the child seemed to be well nourished, but that there were evidences of extensive disease of the placenta.

The hour for adjournment having arrived, the Section repaired to the rear room, where, from a table bounteously loaded, fluids and solids good for the constitution and for local application were administered to willing patients.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, October 6, 1876.

Dr. E. G. Loring, President, in the Chair.

A COMPARISON OF THE VARIOUS METHODS OF TREATMENT IN PERTUSSIS.

Dr. P. B. Porter read an interesting paper upon the above subject, in which he stated that in 1872 and 1873 he had published articles in reference to the treatment of whooping-cough by chloral, and at the same time expressed the opinion, based on clinical study, that it was a most efficient remedy in that affection. After giving it a still further and altogether very extensive trial, he had seen no reason to change his views in that respect. He then proceeded to detail a number of cases in which chloral had been employed. As a rule, the treatment was commenced about the end of the first week of the paroxysmal stage, which is the period when the severity of the disease usually occasions alarm on the part of the mother, and induces her to seek medical advice. In all, the effect of the chloral was marked in its immediate influence on the distressing symptoms, and doubtless the duration of the disease would have been still further shortened had the remedy been used with sufficient pertinacity. In some of the cases the whooping entirely ceased in from five to six weeks, in others in about a week, and in others in one or two days.

More recently Dr. Porter had been experimenting with quinine and the fluid extract of *castanea vesca*, and he then gave the history of quite a large number of cases in which those agents had been used. Without assenting to the views of Prof. Binz in regard to the pathology of pertussis, which Dr. Dawson had adopted, he had always strictly observed the rules which the latter had laid down for the administration of quinine in this affection.

In summing up the results obtained, the writer said: "Could I have preserved accurate records of all the cases treated by the three remedies, some definite

conclusions as to the time required for the control of the disease by each agent might doubtless have been arrived at. Still, from those here given some idea can be obtained of their action, and I think it will be found from an analysis of them that in the average number of cases where either of the remedies seems to be of advantage, and is given early, the paroxysmal stage is about three weeks in duration. In comparison with the others, however, I am constrained to say that I have found castanea fail in a much larger proportion of cases than either chloral or quinine. But in those cases in which it is really of benefit to the patient, its action seems quite as efficient as either of the others." After alluding to various other methods of treatment which he had not tried personally, he concluded by relating a case in which he had made use of the plan of a single complete etherization, recommended as a curative measure by Dr. S. D. Powell, of this city. The anæsthetic had no effect whatever on the course or duration of the disease, the patient coughing and whooping just as much after as before its inhalation.

After some discussion, the Association adjourned.

Stated Meeting, Oct. 13, 1876.

Dr. Frank P. Foster, Vice-President, in the Chair.

REPORT ON PULMONARY AFFECTIONS.

Dr. E. Frankel made the report, which was a substantial *résumé* of the important papers upon that class of diseases published during the year 1875. The subject, pneumonia, it seemed, had received considerable attention, and one author had described what he called a *primary asthenic pneumonia*, that was recognized by symptoms of which the more prominent were the following: There were certain prodromata, not differing essentially from those manifest in a large number of diseases; the chill was less constant; there was an imperfect infiltration, with inflammatory products of the portions of lung involved; purulent infiltration an almost constant attendant; gangrene occurred with greater frequency than in any other form; upper lobe attacked by preference; symptoms developed that gave it the name typhoid; albuminuria; enlargement of spleen; jaundice more frequent than in ordinary pneumonia; had been called bilious pneumonia; depended upon a specific poison.

The history of certain cases was quoted, illustrative of the occurrence of pyæmia with pneumonia, and in one case a large number of sores appeared upon the surface of the body, which were believed to depend upon cutaneous embolism.

According to the testimony of some, it was thought that the line between capillary bronchitis and catarrhal pneumonia was too sharply drawn.

From the evidence adduced it would seem that vocal fremitus is a symptom not to be relied upon too strongly in determining whether fluid was present in the pleural cavity.

Upon the data offered one would rather incline to conservatism with reference to the operation of thoracentesis in cases of pleurisy with effusion; puncture perhaps was not so harmless as had been supposed, was the opinion of one author.

It seemed to be substantiated that about one-half of the cases where the effusion was purulent were followed by recovery, after a free incision through the chest-walls, and intermittent washing out of the cavity.

Attention was directed to the report of a case of primary cancer of the lung. The author quoted believed that primary cancer of the lung admitted of no differential diagnosis from pleurisy with effusion.

The opinion had been expressed by some writers that syphilitic bronchitis and chronic pneumonia following, as a general predisposing cause of phthisis, was not so important as supposed. The course of syphilitic phthisis has been said to be slower than other forms. The communicability of phthisis from husband to wife, and from wife to husband, was referred to, and it seemed that the former was more common than the latter, and could be explained upon the ground of infection through the seminal fluid and the fœtus. Those wives who escaped impregnation were more likely to escape the phthisis.

The report closed with a reference to the use of compressed air in the treatment of pulmonary affections. No discussion ensuing, the Association adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Sept. 27, 1876.

Dr. Charles K. Briddon, President, in the Chair.

The Secretary presented a specimen of spontaneous rupture of the uterus, in behalf of a candidate for admission.

DRY CARIES OF KNEE-JOINT.

Dr. Mason presented a knee-joint, removed by excision from a married woman, aged nineteen years, a patient of Roosevelt Hospital. When seven years of age, the patient said she had a severe attack of illness, which lasted ten months, and at the end of that time she was unable to bear her weight upon her right leg, in consequence of the severe pain which such efforts caused. She was then carried about in her mother's arms for a year, when she began to walk again, the joint remaining considerably stiffened.

Two months before her admission to the hospital, she slipped upon the floor and injured her "weak knee" so severely that she was unable to rest the foot upon the ground. This condition continued until Dr. Mason saw her. She was then very much worn down by pain, was markedly anæmic, and was advanced to the second month of pregnancy. On examination, there was found a subluxation of the knee, outwards and backwards, and the leg was flexed up on the thigh. The joint presented little or no swelling, but the whole limb was atrophied. The joint itself was painful to the touch, and on motion distinct crepitus was elicited. Her general condition improved with great rapidity while in the hospital, so that she was fit for the operation of exsection, which was performed April 14th, by the anterior oval incision. The joint surfaces were almost entirely dry, and presented a beautiful illustration of dry caries. The patella was discovered to be diseased, and was removed with the other portions. The surfaces were brought together by silvered copper wire, the limb placed on a narrow posterior splint, and the whole limb enveloped in plaster-of-Paris dressing. The improvement was astonishing, so that six weeks after the operation the sutures were removed, the wounds had healed, and the union was firm. On the 3d of July the splint was entirely removed, and in August she left the hospital.

Dr. Mason presented a drawing of the limb before the operation, and a photograph of it after the operation. The shortening was found to be somewhat more than an inch, without taking into account that the

right limb was shorter than the left. As far as Dr. Mason had been able to ascertain, this was the second case on record in which the operation had been performed during pregnancy. The first was done by Mr. Gant, of London, and at the same period of gestation.

GELATINOUS SYNOVITIS.

Dr. Mason exhibited photographic representations of a case of gelatinous synovitis of nine months' standing, for which he had also performed exsection. The subject was a single woman, aged 22 years. The operation was done on the 16th of February last, after the same method of the latter case, and with the same kind of dressing. Union was firm at the end of six weeks. April 18th she was up and about on crutches, and on the 28th was out on a pass, and from that time until July, when she left permanently, she was out daily. The shortening was just one inch and a quarter.

In both cases the antiseptic plan of treatment was adopted, the joint being syringed out daily with a solution of salicylic acid, one part to three hundred.

LIPOMA IN A CHILD.

Dr. Frankel presented a fatty tumor, the size of a lemon, which he had removed by operation from the middle and outer third of the clavicular region of a child, aged four years. The operation was performed by the antiseptic plan, under carbolic acid spray. The wound healed by first intention. The patient was not more than ordinarily plump, and there were no signs of fatty accumulation in other parts of its body, neither was there any hereditary predisposition to lipoma present. The point of interest was in the age of the patient.

THE DEVELOPMENT OF CANCER CELLS.

Dr. C. Heitzmann presented microscopic specimens of cancer tumors of the mammary gland and the skin of the parotid region, in order to illustrate the history of development of cancer-elements. This subject has been studied in his laboratory by E. W. Hüber, of this city, and the results published in the Transactions of the Imperial Academy of Sciences in Vienna, vol. lxxii., 1875. The two main views about the formation of epithelial elements, characteristic for cancer, are: that of Virchow, who advocates the development of such elements from the "cells" of connective tissue, while recent investigators, as Thiersch, Waldeyer, and others, maintain that epithelial elements always are the offspring of former epithelium. H. shows that the first formed elements in the embryo are all alike, and the differentiation into peculiar tissues takes place afterwards from those in different elements. Just like in the inflammatory process, even in the growth of tumors; first of all, an indifferent tissue is formed, giving rise to production of distinct forms of connective and epithelial tissues. In cancerous tumors we meet very often with spaces within the connective tissue, closed on all sides and filled with epithelium; no connection whatever can be demonstrated between the newly-formed and the glandular epithelium. The theory of immigration could not explain the gathering of cancer-elements, as epithelium, if ready formed, is not liable to migrate, a property due only to indifferent corpuscles. Then we see in certain forms of cancer groups of epithelial elements separated from each other by elastic fibres, which in normal condition occur only in connective tissue. This is a striking proof for the fact that former connective tissue changed into a cancerous one. The theory of Virchow, therefore, has to be maintained, with the addition that not only the "cells" of connective tissue, but the whole amount of living matter within the basis-substance, is capable of production, and the results of this production can be, under certain conditions, the cancer-elements.

EXSECTION OF ELBOW-JOINT.

Dr. Briddon presented an exsected elbow-joint, and read the following notes of this case, for which he was indebted to Dr. A. F. Buehler, of the House staff, Presbyterian Hospital.

Maggie Shea, æt. 26. Ireland. Married. Housekeeper. Admitted August 26th. She states that the first symptoms of her present trouble began to manifest themselves about a year and a half ago. At that time she was in perfect health, and has no recollection of having received an injury, nor can she assign her present disease to any cause whatever. She then complained of pain whenever she attempted to move her elbow; this pain increased in severity; became excruciating, so as to rob her of her nights' rest. The elbow now began to swell up, and an abscess formed opposite the external condyle of the humerus. After a time patient noticed that her elbow was growing stiff, and that she could move her arm but with difficulty. This stiffness increased so that one year ago she was unable to move her arm at all. She then applied for aid at the Demilt Dispensary, where the abscess was opened, the presence of dead bone detected, and where subsequently a portion of the external condyle was removed by Dr. Satterthwaite. This operation relieved her considerably, so that she was enabled to perform some of the lighter household duties. Gradually, however, the stiffness again returned.

Patient was admitted to the hospital on August 26th. On examination it is found that the elbow is somewhat swollen; that two fistulous tracts traverse the soft tissues covering the external condyle, to terminate at dead bone in the joint, and that marked angular fibrous anchylosis exists, the arm and forearm forming an angle a little less than a right angle, and causing a perfectly useless joint. Patient also complains of pain occurring at intervals of days, and which is most severe at night.

August 31st.—It had been decided to operate upon the patient to-day, but as she was suffering from intercurrent attacks of inflammation, in which the joint puffed up, attended by the formation of abscesses and elevation of temperature, it was thought advisable to postpone the operation until September 7th. Poultices have been applied to hasten suppuration.

September 5th.—Patient this morning has had a slight attack of inflammation and severe pain in the joint. She was ordered tinct. aconit., gtt. ½, every two hours. Her evening temperature was 100°.

September 6th.—Patient's temperature normal. Poultices were discontinued this evening.

September 7th.—Operation by Dr. Briddon.—Patient being placed under ether, a free vertical incision was made, being about four inches in extent, taking for its centre the olecran process, and dividing the soft tissues down to the bone. The soft parts were then carefully separated from the bones, and the dissection was then carried around the olecranon, closely hugging the sides of this process, so as to avoid the ulnar nerve. The articular ends of the bones were then turned out of the joint. It was then found that all the bones entering the elbow-joint had undergone carious action. The head of the radius and sigmoid cavity were then removed by means of a chain-saw, care being taken to avoid the insertion of the brachialis, anticus, and bi-

ceps muscles; the condyloid surface of the humerus, being diseased, was removed in the same way. After arresting the hemorrhage the incision was then closed, with the exception of a space of about one-half inch in the middle, into which a tent of lint, saturated with carbolized oil, was introduced, so as to leave an opening through which drainage might be established. The arm was then placed upon an angular splint, to secure absolute rest. Patient very readily recovered from the effects of ether and operation. In the evening she complained of severe pain at the elbow, which was relieved by hypodermics of morphine. Cold-water dressings have been applied to the joint. Evening temperature, 100.5°.

September 8th.—Patient is doing very well, but is annoyed by a sense of numbness in her fingers, which is attributed to the application of the Esmarch bandage. The swelling around the joint is inconsiderable. Temperature in the morning, 99.8°. Evening, 102.2°.

September 10th.—This morning a portion of the tent which had loosened, together with most of the sutures, were removed. Morning temp., 100.8°. Evening temp , 100°.

September 11th.—The remaining portions of the tent and of sutures being removed, a free discharge of pus followed. A new plug of vascum was introduced, and it was ordered to have the wound syringed out twice a day with a weak solution of carbolic acid (3 j.—Oj.). Morning temp., 99°. Evening temp., 99.20°.

September 13th.—The joint to-day looks very well; there is very little swelling, and discharges freely. The numbness in fingers is diminishing. Morning temp., 98.8°. Evening temp., 99°.

September 18th.—Since September 13th the patient's condition has been steadily improving, the swelling has subsided, and the temperature has not gone beyond 101°.

September 24th.—The temperature to-day rose up to 102°, and a small abscess formed around the outer part of the joint, which was opened. Since then patient is doing well.

Dr. Satterthwaite remarked that the patient presented herself to the college clinic two years ago, with what appeared to be simple caries of the external condyle. Iodine applications were made to the part and specific treatment employed with good result. At the end of six months after the supposed cure the disease returned, when she presented herself at the Demilt Dispensary, when the same treatment was continued with benefit. An operation was advised, but, being advanced in pregnancy, the patient declined its performance. After the birth of the child she presented herself again for treatment, when the disease was found to involve the joint, and she was sent to the hospital.

Dr. Briddon supposed that the origin of the disease was in caries of the condyle, and that the joint became subsequently perforated.

Dr. Mason remarked that, especially in gelatinous degeneration of the joints, it was very difficult, and oftentimes impossible, to get crepitus. He then related a case in point of disease of the tarsal joints, in which no such crepitus could be discovered; but at the operation the whole of the three cuneiform bones and a portion of the cuboid were destroyed.

(To be continued.)

Frederic William Godon, M.D., late of this city, died at San Rafael, Sept. 23, after a brief illness. Deceased was a native of Philadelphia, and a graduate of Harvard and Bellevue Hospital Medical College.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 22 to October 28, 1876.

McClellan, Ely, Surgeon. To proceed to Columbia, S. C., and report in person to the Department Commander. S. O. 152, Dept. of the South, Oct. 19, 1876.

Forwood, W. H., Surgeon. To report in person to the Commanding Officer, Dept. of the South, for assignment. S. O. 219, A. G. O., Oct. 21, 1876.

Hall, J. D., Asst. Surgeon. To accompany battalion of 1st and 3d Artillery to Columbia, S. C. S. O. 206, C. S., Mil. Div. of the Atlantic; and assigned to temporary duty at Columbia, S. C. S. O. 156, Dept. of the South, Oct. 24, 1876.

Ewen, C., Asst. Surgeon. To accompany battalion of 3d Artillery to Columbia, S. C. S. O. 206, Mil. Div. of the Atlantic, Oct. 18, 1876; and assigned to duty at Aiken, S. C. S. O. 155, Dept. of the South, Oct. 23, 1876.

Ainsworth, F. C., Asst. Surgeon. So much of S. O. 182, C. S., from A. G. O., as accepts his resignation to take effect Nov. 10, 1876, is revoked. S. O. 219, S. C., A. G. O.

Buell, J. W., Asst. Surgeon. To accompany Co. "A," Permanent Party from Columbus Barracks, Ohio, to Columbia, S. C., S. O. 155, Fort Columbus, N. Y. H., Oct. 19, 1876, and assigned to duty at Blackville, S. C. S. O. 155, C. S., Dept. of the South.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending October 28, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Oct. 21	2	14	23	1	3	46	1
Oct. 28.....	0	11	28	1	19	39	1

Warts.—Chromic acid is probably the best local application for warts.

Wakefulness.—Dr. John L. Cook, of Henderson, Ky. (*Louisville Medical News*), proposes a remedy for lowering the pulsations of the heart in insomnia by taking deep and slow inspirations. We suppose these should be continued until the patient gets asleep.

Bromide of Potassium disguised in Milk.—It is claimed by a writer in the *Medical Times*, that one ounce of milk will disguise the taste of twenty grains of bromide of potassium, and will effectually prevent the disagreeable sensation of burning in the stomach experienced by patients after taking the dose.

Doctors in the French Army.—The French Minister of War has decided that physicians and pharmacists provided with diplomas, and the interns of the large hospitals, who may be liable to service in the reserve, will only be required to serve in their professional characters, and not as simple soldiers. Those who cannot be utilized professionally will be allowed to remain at home.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 11, 1876.

MEDICAL WOMEN.

THE King and Queen's College of Physicians of Dublin has at length determined to admit a woman to its privileges of license. Although this fact startles some of our English brethren, we believe that the college has not taken a very dangerous departure. We see no reason why it should not, like medical institutions in this and other countries, share the responsibility of solving a vexatious question. It is useless to rail against the women studying medicine. They will do it in spite of male opposition, and have a right at least to try.

They believe they have a sphere in medicine, and we should rather help than hinder them in finding it. Whether they are specially fitted for medical work is not now the question, but whether we will give them an opportunity to work out their own salvation. If we persist in persecuting them, we must only wait the longer for the problem to be solved. The *Lancet* says: "We believe woman's work is to console and support man, not to usurp his functions." This view is eminently sound, and as a general rule is admitted by all. But all general rules have their exceptions, and it is with these exceptions that we mainly have to deal. It is useless for the *Lancet* to say that "unwomanly women alone can aspire to unwomanly work," for it has no effect. The women view the question from an altogether different stand-point, and are willing to shoulder all the opprobrium of the new situation. It is entirely gratuitous for us to bewail their sacrifice of the tender qualities which we call lovable and womanly; if such be sacrificed, what real responsibility have we in the matter? The simple fact narrows itself down to this: some women believe that they are specially qualified to study medicine, and as a profession we believe to the contrary. Neither party can be satisfied until a fair trial is allowed. The right for a trial no one must deny, and the college in question does no more than grant it. The English profession will not be ruined by the course adopted, neither will any extraordinary number of women avail themselves of the advantages offered.

In New York we met the issue long ago, and would have settled the question if we were not forced to acknowledge that "one swallow does not make a summer." It is true that we have a very fine specimen of a swallow, but the summer is not yet.

THE IMPROVEMENT OF IDIOTS.

THE improvement of the condition of idiots and feeble-minded children invests itself with a special interest in connection with the formation of an Association for that purpose, and composed of gentlemen who have already devoted the greater portions of their lives to its study.

The very organization of such an Association promises the best of results by the intelligent centralization of ideas and purposes. A great deal of very valuable information concerning the unfortunate class of children is scattered in the case-books of physicians all over the land, and it is time that it should be turned into the channel where it can do the most good. We are happy to say that the Association so far appreciate the value of such information, that it has made an appeal to the profession at large for every fact of observation or experience which may tend to throw any light upon the general subjects of causation and treatment.

The circular to which we refer is merely a general solicitation for information, leaving the particulars which each gentleman may care to contribute to his individual discretion. The gentleman to whom these answers should be addressed is J. Kerlin, M.D., Secretary of the Association, and Superintendent of the Institution for Idiots, Media, Penn. We hope that our readers will do all in their power to help along the good work and give it the substantial encouragement which it deserves.

It should be a matter of special congratulation that the gentlemen composing this Association are acknowledged experts, and are abundantly able, as well as willing, to utilize all the new facts which may be placed at their disposal. In fact, at the very commencement of its labors we are warranted in predicting for it more than ordinary success. It must soon be looked upon as an authoritative body, not only by the profession, but by the people at large, and its opinions must be respected accordingly. The individual members have already done much to improve the condition of the idiot by judicious physiological training, and have succeeded, even through these weak vessels, of proving the great differences between practical and theoretical education. None, however, are more painfully aware of the necessity of even greater improvement; and, appreciating such a necessity to its fullest

extent, they ask their medical brethren to come up and help them.

MEDICAL SUPERVISION IN SCHOOLS.

The Boston Board of Education has appointed a committee to report upon the advisability of a medical inspector of schools. If this committee wish to reflect the sentiment of the medical profession and of an enlightened public, there is but one result to be anticipated. We imagine, however, that there is to be no difficulty in using the proper arguments at the proper time and in speedily initiating the desired reform. In the meantime our own Board of Education is stupidly stubborn on this vital question. But the time is not far distant when what may now be a matter of choice, may be changed into one of compulsion.

THE OUTSIDE ESTIMATE OF AMERICAN MEDICINE.

Our English cousins who honored us with their presence at the Medical Congress are well pleased with the treatment they received. Their comments upon the success of the undertaking are frank and generous, leaving no doubt of the most cordial appreciation of our endeavors to make their visit agreeable and profitable. The English journals without exception speak of the Congress as a great success, and congratulate the managers accordingly.

The foreign delegates are at the same time willing to acknowledge that American surgery and American medicine are as progressive as are the same departments in their respective countries.

Our skill in operation and ingenuity in contrivance are matters of cheerful acknowledgment on the part of our foreign visitors, and it should be our highest aim to continue to deserve our good reputation. Our institutions, medical museums and medical libraries have received their full share of encomiums. Mr. Adams, delegate from the Medical Society of London, lays his brethren on this side of the Atlantic under particular obligations for the handsome manner in which he has referred to doings in and out of the Congress. On his return to London, and on the occasion of his resuming the chairmanship of the Society after his vacation, he occupied the whole session with an account of his visit to America, and of his appreciation of American talent and American enterprise. His nomination of four distinguished American medical men to the honor of corresponding fellowship was very judiciously and worthily made, and reflects a compliment upon the entire profession of this country.

The Colleges in New York are well patronized. Each institution claims to be doing better than last year. The clinics at the hospitals are well attended. The professors appropriate evenings in the week for quizzing the classes, and are more than ordinarily anxious to give the students every opportunity for improvement.

Progress of Medical Science.

Treatment of Typhoid Fever by Ergot.—At the meeting of the *Association Française pour l'avancement des Sciences*, of August 23d, M. Dubouć, of Pau, stated that he had treated a number of cases of typhoid fever with ergot, and that his success has been satisfactory. The toleration of ergot increases with the severity of the disease. As a rule the drug is not so well tolerated by women as by men; consequently, it must be given in smaller doses to the former. It may be given without fear to pregnant women. The pulverized ergot of rye preserves all its medicinal qualities for about eight days; if it lose its physiological properties within that time, it is because it was already altered when pulverized. Of fifteen cases treated by Dr. Dubouć, the extreme rapidity of the cure rendered the diagnosis of two uncertain; five cases of moderate gravity that recovered presented during their courses alternations of aggravation and amelioration that corresponded with intentional interruptions of the treatment. Of eight very grave cases, six recovered; three of these cases being already far advanced before the ergot treatment was begun. In the two fatal cases the ergot did not produce its ordinary therapeutic effects, and on examination it was found to be worm-eaten and covered with a grayish powder.—*Gazette Hebdom. de Méd. et de Chir.*, September 1st.

Diabetes a Cause of Phymosis.—M. Bourgade has observed four cases of phymosis due to the irritating action of the saccharine urine of diabetes upon the meatus, the gland, and the prepuce. That saccharine fluids are irritating is proven by the frequency of papular and vesicular eruptions on those parts of the body that are usually uncovered among workmen in sugar factories. Surgical operations for the relief of the phymosis in these cases are useless as long as the cause persists. The first indication is to remove the cause, and when this is done the phymosis will often disappear spontaneously. M. Bourgade thinks that a phymosis complicated with a balano-posthitis should never be operated on before the urine has been examined for sugar. M. Verneuil has also seen two cases of diabetic phymosis, and agrees with M. Bourgade as to the inadvisability of operating. A confrère of his had lost two cases on which he imprudently operated for diabetic phymosis.

We may add here that M. Comillon, of Vichy, reports three cases of diabetes complicated with inveterate fistulas and large ulcers, which had existed for a very long time, in which the local affections disappeared in a few days under the influence of the alkaline treatment. The diabetes was ameliorated, and the improvement immediately extended to the local affections. Cicatrization took place in one case in three days, in another in five days, and in the third in eight days. M. Comillon thinks that the diabetic ulcers should be considered a distinct variety, as well as the varicose and the tuberculous ulcers.—*Le Progrès Médical*, September 2d.

Lesion of the Cerebellum and Diabetes Mellitus.—In a fatal case of diabetes mellitus, which was treated in Mosler's clinic, and in which there had been no disturbances of sensation, or motion, or of the special senses during life, the autopsy revealed a well-marked spot of inflammatory softening about the size of a pigeon's egg, in the nucleus dentatus of the left hemisphere of the cerebellum. The theory of the

neuropathic origin of diabetes rests on sound practical grounds, and there can be little reason for doubting that in this case the increased secretion of sugar was excited by the central affection, especially as Eckhard has shown that injury of the second lobe of the vermis cerebelli in rabbits will artificially excite diabetes. It is strange that such a well-marked lesion was not attended by any signs of disease of the central nervous system during life.—*Berliner klin. Wochenschrift*, July 10, 1876.

Corrosive Sublimate as a Remedy for Gonorrhœa.—During the last three years, Dr. Leopold Brück, of Buda-Pesth, has given the bichloride of mercury a systematic trial in the treatment of blennorrhœa urethræ, and the following are the results of his experience:

1. Under the use of the sublimate, gonorrhœa is cured within six weeks, without the supervention of any of those complications that are met with when the treatment by injections is employed. The use of the remedy may be begun in the so-called hyperæmic stage. The discharge is very profuse during the first ten days, and then gradually becomes less profuse and more serous; the burning pain and the chordee are not severe.

2. Spirits, coffee, and highly spiced foods must be avoided during the treatment.

3. Purgatives are not required while the sublimate is being used.

4. The remedy sometimes causes cramps in the stomach and small intestine, and its use must then be intermitted for some days.

5. It must not be used when there is disease of the heart or lungs.

The sublimate should be given in pill form. During the first 10 days, 20 pills, containing each $\frac{1}{12}$ gr. of mercury should be given; the next 20 pills should contain $\frac{1}{10}$ gr. of the medicine, or they should be taken in half the time if the quantity remain the same.—*Centralblatt für Med. Wissenschaften*, July 1, 1876.

Bicarbonate of Soda in Suppression of Urine.—Dr. Dickinson, in his lectures on albuminuria, says, that "in that rapidly fatal form of nephritis, in which the tubes become widely sealed up as if with molten glass by a pseudo-croupous exudation of fibrin, while the urine is loaded not only microscopically, but as a bulky precipitate, with large fibrinous cylinders, all plugging from this cause can be prevented by alkalies." Mr. Semon Lane, of Dunfermline, states, in this connection, that he has used the bicarbonate of soda in a great many cases of renal disease with success, and reports a few cases of suppression of urine to illustrate its good effects. In the first case, the patient, a previously healthy strong man, was suffering from acute nephritis. His face and extremities were œdematous; he complained of pain in the back, and a constant desire to urinate; his urine was very scanty, about four ounces being passed in the twenty-four hours, acid, loaded with albumen, and contained casts, renal epithelium, and blood. Half a teaspoonful of bicarbonate of soda was given three times a day, along with a diaphoretic and a warm bath every night, and in five days the urine was normal in quantity, alkaline, quite clear, and without a trace of albumen. In the second case, the patient, who had suffered for three years from profuse suppuration due to caries of the spine, passed only six to eight ounces of acid, highly albuminous urine in the twenty-four hours. He had general anasarca and œdema of the lungs. Half a teaspoonful of bicarbonate of soda was given thrice daily, and in three days his urine had increased very greatly in quantity, was alkaline and free of albumen, while the œdema had greatly diminished. A third case was one of general anasarca, after scarlatina in a child three years old. His urine was highly albuminous, bloody and scanty; his temperature was 103°, and he complained of pain in the back and great nausea. He took one-fourth of a teaspoonful of bicarbonate of soda, three times a day, and was bathed every night. In exactly a week he was quite well, though feeble and anæmic.—*British Medical Journal*, July 15th.

The Arthropathies of Locomotor Ataxia.—M. Raymond has examined a number of joints and bones that became diseased in the course of this affection, and directs attention to the process of atrophy and destruction that affects principally the most projecting parts. This atrophy is not accompanied by osteophytic deposits as is *e. g.* ordinary arthritis deformans, and the individual parts in the latter affection do not so completely lose their normal forms as they do in the ataxic disease. In this the ligaments, as such, disappear, and in their place a dense connective tissue is developed; the muscles in direct opposition with the bones are atrophied, and have undergone fibrous or fatty degeneration. The fluid contents of one of the diseased joints consisted of a reddish serum that contained a few red and white blood-corpuscles and hæmatoidin crystals. Muriatic acid and heat showed that it contained large quantities of albumen.—*Centralblatt für Med. Wissensch.*, September 16th.

Clinical Study of Diphtheria.—At the late session of the *N. Y. State Medical Society*, Dr. Bayles, of this city, read a paper on the above subject, in which he endeavored to prove that diphtheria is primarily a constitutional disease, and that it is in all probability autochthonous and not excited by a specific germ poison. His observations were based on twenty cases of the disease met with in dispensary practice. In all these cases he found that there had been a deterioration of the health and strength for a varying period before the appearance of the disease, and after the commencement of the disease, all, with perhaps one exception, were seen before the appearance of membrane in the throat, and many even before the appearance of the catarrhal throat symptoms. The symptoms these cases presented, were, quick, irritable pulse, high temperature, cool extremities without moisture of skin, pallor, rather slow respiration, nausea, and sometimes vomiting, diarrhœa, somnolency, irritable temper, and scanty urine of high specific gravity and loaded with urates. In each of these cases the doctor made a slight abrasion of the cutaneous surface at some distance from the usual seat of local lesion, and in every case after a short interval a membranous patch covered the surface of the wound. In one case this was done to verify the diagnosis after the throat lesions had appeared, but in all the others the traumatic exudative patches preceded or appeared simultaneously with the faucial patches or the nasal flux. The appearance of those patches on the body is a certain diagnostic sign of diphtheria, and the fact that they preceded the formation of faucial patches in some cases, demonstrates beyond question the primarily constitutional nature of the disease.

With regard to the etiology of the disease, Dr. Bayles is convinced by his observations that the disease is autochthonous, and neither depends upon nor is propagated by a specific contagion received from without. A predisposing cause is to be found in the noxious influence of bad air, bad food, and uncleanliness, acting on an already impaired and badly sustained system. The fact that many persons in a family often suffer in

turn from the disease does not militate against this theory, for all the members of the family are generally exposed to the same noxious influences. The infrequency, not contiguity, and slow multiplication of Dr. Bayles' cases, excluded the idea of an epidemic, and in no case could he, on the closest scrutiny, find one sufficient local cause for the disease.

All of Dr. Bayles' cases recovered, a result which he seems inclined to attribute to the early and active constitutional treatment to which they were subjected. As soon as the diagnosis was made, he gave a single dose of from ten to thirty grains of calomel as a sedative and alterative. The dose for infants was smaller. Two hours after this he gave a powder containing one grain of quinine and three grains of Dover's powder, and repeated it every hour until free diaphoresis was produced, and then at intervals of two or three hours, for twelve hours longer. This was to supplement the action of the calomel, and, at the same time, support. He then gave the elixir iodo-bromide calcium compound, in doses of a teaspoonful every two or three hours until convalescence was established. This medicine he considers as a valuable general tonic and alterative. When possible, he used the same medicine mixed with water as a spray or gargle, but employed no other local treatment. Milk was the chief food allowed, with the addition of a little brandy from the third day. Lastly, the body was bathed two or three times a day with a tepid lotion of salicylic acid, partly as a concession to the disinfectionists.—*Virginia Medical Monthly*, September.

The Originator of the Double-curved Midwifery Forceps.—With the exception of Johanne Mulder, all the prominent English, American, and Continental writers on the history of the forceps, give the credit of adding the pelvic curve to Levret or Smellie. Dr. McClintock, however, at a recent meeting of the *Dublin Obstetrical Society*, proved that the merit of this change in the construction of the forceps really belongs to Dr. Benjamin Pugh, of Chelmsford, England. Levret indicated in a work published in 1747 that he had given a new curve to the forceps, but he did not publish a description of his improvement until 1751. Smellie was led to give his forceps the pelvic curve, by his experience in a case that occurred in 1752. Dr. Pugh, however, in a book published in 1754, but evidently written four years earlier, gave descriptions of long and short double-curved forceps that he had invented upwards of fourteen years before. This carries us back to the year 1736 as the date of Pugh's invention. It is evident, then, that, although both Levret and Smellie probably thought their inventions original, the credit for the priority of the invention really belongs to Dr. Pugh.

The Nerve Terminations in the Electrical Apparatus of the Torpedo.—In this paper M. Rouget combats the statements of Ranvier, that the electric nerves in the torpedo terminate in the electrical apparatus exclusively by free ends, and never in a closed network (Kölliker, M. Schultze). M. Rouget recommends the use of a seven per cent. solution of nitrate of silver on the fresh tissue, as a sure method of demonstrating the constant occurrence of a closed network. Remak is cited by Ranvier as an authority for the free ending of the electric nerves, but Rouget believes that at the time Remak made his observations (fifteen years ago) the optical and technical aids at the command of the observer were not sufficiently powerful to decide this question. The somewhat confused statements in Remak's text is a proof of this.—*Centralblatt für Med. Wissen.*, September 16th.

Reviews and Notices of Books.

Autumnal Catarrh (Hay-Fever), with illustrative maps. By Morrill Wyman, M. D., late Hersey Professor Adjunct of the Theory and Practice of Medicine in Harvard University, etc., etc. New York: Published by Hurd & Houghton. Cambridge: The Riverside Press. 1876

Hay-Fever; or, Summer Catarrh: Its Nature and Treatment. By George M. Beard, A.M., M.D., Fellow of the New York Academy of Medicine; Member of the New York and Kings County Medical Societies; of the New York Society of Neurology, etc., etc., etc. New York: Harper & Brothers, Publishers, Franklin Square. 1876.

Dr. Wyman was one of the earliest investigators of this disease. Perhaps he was stimulated to such investigation because the disease was one of his annual visitors. At all events, something more than twenty-five years ago he gave a description of what he calls autumnal catarrh, and from that time until the present he has been a steady and acute observer of its phenomena, as witnessed by the contributions which from time to time he has given to the profession regarding its natural history. The present volume is brought forward as one containing the result of these many years of careful study and observation. "There are two forms of catarrh," says Dr. Wyman, "and both recur annually. One is known as 'rose cold,' or 'June cold,' 'hay asthma,' 'hay-fever,' etc., and commences in the last week of May or first of June, and continues until about the first week in July. The other is known as autumnal catarrh, because it occurs in autumn. The most prominent features of distinction between these forms of catarrh are two in number, namely, time of occurrence and severity of symptoms. The 'June cold' is a mild disease, and depends upon new-mown hay as the well-marked typical cause. The autumnal catarrh is more severe, cough and asthma being prominent symptoms, and its essential cause is not known. It is to the latter form of the disease that the author directs our attention in the book before us. After the introduction, a general description, or history, of the disease is given, in which the symptoms are enumerated in their order and the principal variations noted. We incline to regard this as a commendable feature of the book. In the sections following an account is given of the local symptoms; such as those relating to the nose, eyes, mouth, and throat, chest, asthma, heart, and skin. Then follows a description of the constitutional symptoms, such as fever, intermittent character of the catarrh, and *impression upon the nervous system*. Associated with this is a tabular comparison of groups of symptoms with reference to their frequency of occurrence; and it is seen that there is a preponderance of the affection of the eyes, nose, ears, and throat, over the other groups. Upon these pages—and it is another commendable feature of the entire book—clinical foot-notes are added, illustrative of each symptom described in the text. It amounts to demonstrative teaching, which is always convincing.

Succeeding these are several sections devoted to the study of the annual course of the disease. Here we find the three stages of the affection described, namely, the *catarrhal*, the *bronchial*, and the *spasmodic*. The author recognizes the existence of premonitory symptoms, but does not deem it necessary to introduce what other authors have called a *premonitory* stage. The

author then presents what he is pleased to call the "geographic and chorographic relations" of the disease, and these sections are accompanied by maps upon which are indicated the regions in the U. S. where the disease prevails, as well as those in which the sufferer is comparatively, if not entirely, exempt. These pages afford evidence of extended and prolonged research. The probable correctness of such chorographical indications is distinctly recognized by Dr. Wyman, and, in one place, he speaks of the probable exemption from catarrh at Peterboro, Madison Co., N. Y., situated upon the great Pennsylvania and Ohio plateau. On a still higher elevation, upon the same plateau, and a few miles from Peterboro, cases of "June cold" have occurred, however, and one which the reviewer calls to mind was cured entirely by removal to Cedar Falls, Iowa. Now, by referring to Dr. Wyman's maps, it can be seen that Cedar Falls is situated upon the border line between the catarrhal and non-catarrhal regions; but whether our old friend is just over the border and looking disparagingly towards the east, we are unable to say, but suppose that she may be. The maps, however, were made for study with reference to autumnal catarrh, and the reason for introducing this case of June cold will be seen hereafter. In general, place has a marked influence on the disease, and the mountains and the sea are resorts where the sufferer can escape the torments of this annual visitor. Elevation, however, is not the only element of prevention. Some patients are very much benefited by resorting to large cities during the months when vegetable pollen is most abundant, a fact that argues somewhat in favor of the disease being of vegetable origin. Under the head of "cause," Dr. Wyman has first presented what is known regarding the essential nature of the disease, and concludes by rejecting hay as a cause, and states that the essential cause is not known. He believes, however, that the disease is hereditary, and under the head of individual predisposition he almost says that it should be regarded as essentially of *nervous* origin. For, on making inquiry as to the system or systems in which this predisposition may lie, the author says: "'The speedy disappearance of all these symptoms,' and 'the suddenness of the attack' without the usual signs of inflammation, certainly correspond better with what we know of derangements of the nervous system than with those of the mucous membrane or the organs by which it is invested." The author admits the unquestionable subsequent implication of the mucous membrane, and that the tissue may become "temporarily hypertrophied or even permanently thickened." Several pages are devoted to the sensitive nervous system under the head of causes. First admitting that there is a peculiar individual predisposition, Dr. Wyman believes no advance has been made as to the cause of the outbreak at certain seasons of the year and no other. The exciting causes, or what the author calls "causes of paroxysms," such as dust and railway smoke, never develop the peculiar symptoms except during the critical period. The suggested relations which heat, strong sunlight, and electricity have to autumnal catarrh as causes, are then discussed, and the conclusion reached that of the origin of this singular disease but little is known. Under the head of causes of paroxysms, the evidence in favor of vegetable and animal origin is considered, as well as dust, heat, bright sunshine, fruits, fragrance of flowers, etc., etc. In this connection three interesting questions are asked: Is it a self-limited disease? Is it a new disease? Is it connected with civilization? It is believed to be self-limited only when not properly treated. The answers to the other questions, propounded by the author, we have not been able to find anywhere in the text. This is to be regretted. Under the head of diagnosis the essential features of difference between autumnal catarrh and ordinary catarrh, bronchitis, pneumonia, local inflammation of the eyes, and June cold, are given, and the symptoms upon which a differential diagnosis is to be based are arranged in columns, side by side, upon the same page. The subject of prognosis is next introduced, and it is thought that autumnal catarrh, either of itself or its complications, has but little influence, generally, in shortening life.

The treatment of this singular disease is summed up as follows:

1. Remain in a non-catarrhal region during the critical period.

2. Strengthen the system by food and tonics.

3. Avoid dust, smoke, night air, and the vicinity of plants known to produce a paroxysm.

4. Dress warmly, with flannels next the skin.

5. For the cough, mild narcotics; various household demulcents.

6. For asthma, smoking strammonium leaves, saltpetre, Espic cigarettes, arsenical cigarettes, inhalation of sulphuric ether, carbolic acid.

A tabular view of one hundred and eighty-five cases of autumnal catarrh is then given, and the volume is finished by giving the histories of fourteen illustrative cases.

Dr. Wyman's book is worthy of diligent study, because it contains the clear and careful statements of one who is evidently conservative in thought, of one who does not first embrace a theory, and then look around for facts with which it can be substantiated. It will be specially interesting to those who are afflicted with the disease of which it treats, and will be a source of pleasure to the scientific reader.

We will now turn our attention to Dr. Beard's book upon "Hay-Fever."

Dr. Beard is one of the latest investigators of this disease. In the autumn of 1873, while associated with a number of hay-fever refugees, the idea of instituting an investigation of the disease was conceived, and the present volume is the result of the labor. The book has been shorn of technical terms, so that the laity, whom the author expects will constitute the greater portion of his readers, can read it with ease. It has been given to the medical profession as a book embracing a new theory concerning the cause of a disease long known, and it also contains a description of a new form of the disease, hitherto undescribed, and which the author calls "July cold." The text is divided into eight chapters. The first is devoted to the history of hay-fever, and contains a *résumé* of the literature of the subject with comments upon the methods of investigation heretofore adopted in the study of this peculiar affection. Dr. Beard in this chapter has also pointed out what he regards as defects in former methods of observation, and attributes the failure to solve the problem of the disease "in part to a want of sufficient number of facts relating to it, and in part to a habit—from which even scientific men are not free—of looking at one side rather than all sides of a subject." We are not quite certain but that the doctor belonged to that class of scientific men, while making his investigations in this direction. He has announced a theory with regard to the cause of this disease, nothing more, however, than one strongly foreshadowed by Dr. Wyman, but whose conservatism does not permit him to give it its positive announcement, and has rejected all others. We are led to the

conclusion, therefore, that his evidence upon this point is positive, at least that it is convincing to himself, and that at once places its advocate on a slippery base to withstand the wave of scientific criticism. When the author claims that the phenomena of the disease cannot be developed unless one of these factors is present, namely, a certain individual predisposition, he has said no more than has Dr. Wyman, when speaking of what he calls "individual predisposition;" nor do we see that he has arrived any nearer to an explanation of why such and such symptoms, common to a large number of diseases, break out only at certain seasons of the year, and at no other, in persons having such an individual predisposition. In other words, Dr. Beard has not brought us any nearer to the essential cause of the disease.

Let us study the book somewhat more in detail. Its author claims that the disease is one that belongs to the modern civilization of the nineteenth century, and bases his conclusion largely upon the fact that the symptoms are so well marked, that it could hardly have escaped notice by the physicians who lived in the preceding centuries.

The literature of quite a number of diseases, however, is very modern, and their symptoms, according to modern methods of examination, are as easily recognized as are those of hay-fever, and yet we know of no one who has claimed that they are diseases of modern origin. Indeed Dr. Beard admits that no longer ago than half-a-century the disease may have escaped recognition for many years. Is it not possible, nay probable, that it escaped recognition entirely prior to the present century, and not that it did not exist? "The author's method of investigation," given in the second chapter, is a step in the right direction; for he has sought for "facts and not opinions," and from such facts he has deduced his general conclusions. The facts were obtained by sending out circulars containing a series of questions relating to matters of fact concerning which the majority of intelligent people are more or less competent to judge.

To this method of obtaining facts, however, we suspect there is an insurmountable obstacle, namely, the answers, in very many instances, at least, must come from those who are entirely incompetent to discriminate between facts and opinions, and will send the latter for the former. "With regard to the number of cases of which statistics should be obtained, it soon became evident," says the author, "that one hundred, or even less, if given in full detail, according to the plan indicated in the circular, ought to be sufficient to enable one to arrive at some definite conclusions," and yet Dr. Beard enters a criticism upon Dr. Wyman's statistics, because they have been made upon only *eighty-one* cases, and of a certain number of those the history had been only partially detailed. What does Dr. Wyman say upon this point? On page four, of the introduction of his book, we find the following language: "Several illustrative cases are given in full, and one hundred are collected in Tabular View" at the end of the volume. "The cases collected and the completeness of the histories," which in another place, the doctor states, were derived "from personal examination of those suffering from the disease, the description being carefully written down, and corrected in their presence," "derived as they are from various parts of the United States, especially the northern section, warrants me in giving a general description," etc. It can be seen, therefore, that the number of cases thought to be necessary by Dr. Beard has been obtained by Dr. Wyman, and with the item of favor that their histories were obtained by his personal examination. Dr. Beard's statistics, therefore, can be turned against him, because of an insufficient number of cases upon which to base them, and also from the additional and very important fact that his histories have been largely obtained from non-professionals, and perhaps incompetent observers. His two hundred cases, according to his own admission, are no more valuable than one hundred fully recorded cases, and such a number has been observed and recorded personally by Dr. Wyman. We find one hundred and eighty-four cases in his tabular view.

In the third chapter are given the statistics of Dr. Beard's two hundred cases, based on the circular of inquiry. This collection of material shows that the author has been actively at work, and he has gathered much that will interest both the general and scientific reader. The author's general conclusions are given in chapter four, and the first is that "Hay-fever is essentially a functional disease of the nervous system." This conclusion is based upon the following facts:—1. "The hereditary character." The disease may be hereditary, but heredity can scarcely be said to qualify it for a position among the neuroses. If so, several, which have heretofore stood without the pale of nervous diseases, must be brought within. This view seems to have been anticipated by the author, for he admits that hay-fever might be a blood disease, and yet be as hereditary as it now is; but taken in connection with the following facts and considerations, the essentially nervous character of the malady he believes established "beyond serious question." 2. "It prevails mostly among those who have a constitutional tendency to diseases of the nervous system." We were not aware that those who suffer from hay-fever, are any more liable to be afflicted with nervous diseases, such as neuralgia, sick-headache, hysteria, dyspepsia, chorea, etc., than those who are exempt from the affection. If so, let us have the statistics to prove it. Again, it is claimed that the disease rarely, if ever, occurs among the poor and laboring classes of our large cities; and yet it cannot be said that nervous diseases are uncommon among that class, or that they do not possess the nervous diathesis. Certainly, as delicate organizations are found among the poor as among the rich, and keen intellects are not a specialty behind brown-stone fronts; and now if the hay-fever is a nervous disease, it must be a peculiar nervous disease, and endowed with the power of selection. It would seem from the author's observations that the disease has a rather aristocratic tendency, and yet he denies that it is "a fashionable disease." 3. "It is peculiar to modern civilization." How do we know? There is no evidence in the book that the investigations have been extended beyond the border where civilization ceases. 4. "The symptoms of the disease through all the stages are largely of a nervous character, and are made worse or better by mental influences." Not long since we had the pleasure of listening to an introductory lecture, in one of our medical colleges, in which the learned speaker alluded to humor as one of the good things to be carried into the sick-room by the doctor, because of the beneficial influence it exerted. We believe that, in almost any condition, the patient can be made actually better by proper mental influence, but were not aware that that fact possessed any special significance in arriving at the cause of the disease. "True enough, symptoms indicative of inflammation," says Dr. Beard, "do appear as the result of this irritation, but it is not necessary or just to argue that they are the disease, or that the disease is of an inflammatory character, because they appear in it."

What hinders from changing the above quotation, so that it shall read as follows: True enough, symptoms indicative of the presence of a nervous element do appear as the result of this irritation, but it is not necessary or just to argue that they are the disease, or that the disease is of a nervous character because they appear in it. There may be a peculiar condition of the system which permits the development of the disease, and, indeed, there may be a peculiar condition of the nervous system, but the same may be said regarding many other diseases, which, at present, at least, are not recognized as nervous diseases. 5. "It is affected for better or for worse largely by those influences that operate through the nervous system," and the remedies which are mentioned as having rendered the greatest service in its treatment are quinine, arsenic, electricity, alcohol, stramonium, opium, and ether. As is well known, these remedies are used in the treatment of a host of diseases outside of those commonly called nervous, and some of them are regarded as sheet-anchors for the medical man. But, it is said that they are "pre-eminently nerve remedies." That may be true, and it may also be true that the good results obtained by their use in the treatment of peritonites, malarial fevers, etc., are because of the peculiar influence they exert upon the nervous system; yet we believe it will be hard work to make the profession place such diseases in the category of neuroses. We think Dr. Beard's argument, in the case under consideration, proves altogether too much. In continuation of his line of argument, the author compares hay-fever with ordinary asthma and sick-headache.

Of the pathology of functional diseases of the nervous system but little is known, hence the author's remarks upon this question are brief. In his remarks regarding the unity of early, middle, and later forms of the disease, the following conclusion is reached: "The symptoms in all three forms are the same in kind, differing, if at all, in degree only." The author believes that we here have but one disease, and we endorse the conclusion for this reason, if for no other: it simplifies our study of it, and avoids needless confusion. We fear that there is already existing too great a tendency towards division and subdivision at the risk of attenuation in the study of disease, and we therefore hail with delight a step towards comprehensive observation.

Chapter V. is devoted to the symptoms and course of the disease; and here we have written substantially what has been written over and over again. The characteristics of the attacks are considered under three heads: 1, The suddenness of their onset; 2, their paroxysmal character; and 3, definite stages with remissions. These are excellent divisions for bringing out whatever phenomena of the disease may have a favorable bearing upon the nerve theory. *Four* stages are made, namely: the *premonitory*, the *catarrhal*, the *bronchial*, and the *spasmodic*. These are substantially those made by Dr. Wyman. Under the head of permanent, or after effects, Dr. Beard states that hay-fever *usually* leaves the mucous membrane in as healthy a condition as it found it, and uses it as an argument in favor of his theory. Dr. Wyman, on the other hand, maintains that the mucous membrane *unquestionably* becomes implicated secondarily, although he gives the reader no idea as to how frequently temporary hypertrophy, or permanent thickening occurs. As to the facts, then, in this particular, the two authors stand upon nearly the same base. Diagnosis and prognosis are taken up in the sixth chapter, and the points in differential diagnosis between hay-fever, common cold, ordinary asthma, and acute bronchitis, are given. With regard to prognosis, it is said that hay-fever is a life-long heritage, and rarely shortens life. The statements made in this chapter are substantially those made by Dr. Wyman in the corresponding chapter in his book, with the exception that Dr. W. has given the differential diagnosis between autumnal catarrh, common cold, acute bronchitis, and June catarrh, and also pneumonia and conjunctivitis.

In the seventh chapter the author presents his views relative to prevention and treatment, and starts off with the commendable effort to disabuse the profession and the people of three serious errors: 1, That death is the only cure; 2, that all medicinal treatment during the attack is useless, or worse than useless; and 3, that some specific may yet be found that will prevent or relieve all cases.

The first error, to a very great extent, has been corrected; for sufferers have learned that there are places of refuge where the enemy does not follow. The preventive and curative influence of the mountains and the sea are now well recognized. The chief aim, therefore, in this chapter, is to correct the second and third errors.

It contains a goodly amount of material which is well arranged, but we fail to note very much that is new. A large number of remedies, and several combinations of remedies are mentioned, that can be used for local and general treatment, and, doubtless, used with very great advantage. Nitrite of amyl is spoken of as a remedy worthy of trial, and is said to be harmless. Upon that point there is some difference of opinion. We also believe that the author will, in the second edition, amend the statement regarding the frequent repetition of two-drachm doses of the muriate tincture of iron. That is beyond Dr. Prout's dose, which the author endeavors to give. Dr. Beard has not attempted to indicate by any map the exempt region, for he does not believe there is any "arbitrary limit of elevation or of latitude." "No mountainous region can afford uniform relief every year for all persons."

The last chapter is devoted to illustrative cases. These, for the most part, were written up by the patients themselves, and, although it is a very unsafe method of obtaing *facts*, instead of opinions, they seem to be very fully and fairly stated. There are some deficiencies, however, in the histories, which could hardly be supplied by patients, perhaps, but which are quite important as aids in arriving at scientific conclusions concerning the nature of the affection. Notable among these is the lack of any thermometrical record, and the rate of pulse and respiration are not given in a single case reported, either by the patients themselves or by physicians. These are important clinical items, and should not have been overlooked, especially in the double effort of establishing the unity of two forms of disease, heretofore regarded as distinct, and giving a new theory with regard to the etiology of these two and a third form hitherto undescribed. Dr. Beard has produced a book, as has been his custom, in a remarkably short period of time since he began his observations upon hay-fever, and we are sorry to say it has the impress of hasty preparation. It is quite evident that he is enthusiastic in the advocacy of a new theory, and we fear that in this instance his enthusiasm has got the better of his usually good judgment, and led him into the delusion that there was no better way of announcing such theory than by writing a book. The result has been that the work contains a large amount of material that is hackneyed, and, it is to be feared,

will not satisfy the scientific investigator, however pleasing it may be to the non-professional reader.

Reports of Hospitals.

ST. FRANCIS' HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

G. M. EDEBOHLS, M.D., HOUSE PHYSICIAN.

THE COLD BATH IN THE TREATMENT OF TYPHOID FEVER.

In patients possessing the average physical strength, and sick with typhoid fever, the cold bath is employed promptly whenever the temperature of the body rises above 103½° F. The patient is immersed to the neck in water having a temperature of 85°–90° F. and cold water is then steadily added until a bath having a temperature of from 58° to 60° F. is obtained. After remaining in the bath from ten to twenty minutes, the patient is removed, rubbed dry, enveloped in a blanket, and put in bed, and an ounce of brandy administered to aid in establishing reaction. The thermometer is used fifteen minutes after the patient has been placed in bed, and the temperature in the rectum in the male, and in the vagina in the female, has, as a rule, been found to have been reduced from 2½°–4° F.

If at any time during the employment of the bath, symptoms of marked prostration supervene,—as evidenced by decided chilliness, lividity of the surface, most readily detected on the prolabia and nails, chattering of teeth, etc.—the patient is immediately taken out of the water, rubbed dry, and warmly covered in bed.

A patient was seen in whom the disease had run its full course twice since his admission to hospital. In the second attack, which was of unusual severity, the cold bath was administered forty-six times in the course of thirteen successive days. The man at the time of the visit was considered as convalescent.

The character of the eruption had been found to be a pretty safe guide with reference to endurance of the baths in any given case. As a rule, when the eruption has been abundant, and of a deep-red color, the reaction after the use of the bath has not been what was desirable, and a few trials has been sufficient to convince the attendants that it was necessary to have recourse to some other form of antipyretic treatment.

QUININE IN TYPHOID FEVER.

In conjunction with the cold bath, quinine might or might not be administered. When, for any reason, cold water is contraindicated, chief reliance has been placed upon the antipyretic influence of quinine. The drug has been used in the following manner: *First.* It has been given in small doses frequently repeated (5 grains every two or three hours). *Second.* Twenty or thirty grains have been administered in one or two doses at the time when the temperature was highest, generally late in the afternoon. *Third.* The same quantity has been administered in one or two doses when the temperature had about reached its lowest point.

Of these three methods, the first had exercised but little influence in controlling the temperature; the second had generally yielded tangible results, in so far as the temperature, taken from one to three hours after the administration of the drug, had generally been found to have been more or less reduced; but the improvement was only transient, and another large dose was soon required. The third method was considered the most judicious, and was the one generally employed. The temperature in cases of typhoid fever has been taken every three hours, in the rectum in males, and in the vagina in females; and the average of the twenty-four hours, in patients treated by the third method, has been found to be lower than that of the cases in which quinine was administered in accordance with the first two.

IODINE IN TYPHOID FEVER.

Iodine has usurped the place of the mineral acids, and is given internally in all cases of typhoid fever. It is thought to lessen the troublesome gastric irritability so often present, and to diminish the number of evacuations from the bowels.

The following formula is usually employed:

℞. Iodinii ..... ʒ j.
Potassii iodidi.... ..... ʒ ij.
Aq. dest..... ʒ x.

M. Gtts. iij. in wineglassful of water every three hours.

Lugol's solution, the liquor iodinii comp. of the Pharmacopœia, may be used in doses of six drops every three hours.

The cold bath, quinine and iodine, with close attention to the diet and the exhibition of stimulants when indicated, constitute the main features in the treatment of typhoid fever. The cold wet pack is occasionally substituted for the cold bath when the latter is not well borne.

ENLARGEMENT OF THE SPLEEN.

Enlargement of the spleen, demonstrated by percussion, has been present as early as the latter part of the first week in all the cases of typhoid fever treated at this hospital during the last two years. Notice was made of this fact, not on account of its supposed singularity, but for the purpose of directing attention to its value in a diagnostic point of view. The enlargement of the organ, it was claimed, could in most cases be ascertained before the appearance of the eruption, and was almost invariably present at the period of the disease when patients generally apply for admission to hospital. When great tympanites exists the spleen may be crowded out of its normal position, and it must then be searched for posteriorly, where it will usually be found lying against the ribs and the side of the vertebral column.

CHRONIC BRONCHITIS WITH EMPHYSEMA—APOMORPHIA.

It has become a sort of routine treatment for cases of chronic bronchitis with emphysema, to administer from one-third to one-half a grain of apomorphia daily, and continue it for some time. It has been given by the mouth, and continued for two or three weeks without annoyance to the stomach. It was believed that the patients did better with than without it, although other medicines were at the same time administered.

INJECTION OF PULMONARY CAVITIES.

In several cases, a hypodermic needle had been thrust through the chest-walls, and into cavities in the lungs, and a few drops of a one and one-half or two per centum solution of carbolic acid injected. *No bad effects have been produced*, and it had seemed to lessen the expectoration and cough, and thus modified the fever.

Correspondence.

MEDICAL CENTENNIAL AFFAIRS.

AMERICAN EXHIBITS—CHEMICAL AND PHARMACEUTICAL PRODUCTS AND MANUFACTURES—PILLS AND THEIR COATINGS—SURGICAL INSTRUMENTS, ETC.

PHILADELPHIA, Oct. 28, 1876.

THE authorities who superintended the classification of the medical exhibits, and their arrangement in groups and special locations, must have been sorely puzzled with the pressure from United States exhibitors for space and choice of position. They must have been seriously agitated, also, as to the point at which to draw the line which would exclude from the display the cheap or flimsy wares of the mere advertising charlatan, who would greedily occupy every inch that might be allotted to him. I think that, as a rule, a proper distinction has been made, and the process of exclusion sensibly and judiciously effected to prevent some of the vendors of proprietary medicines from flaunting their pretentious claims in the faces of their more creditable and refined neighbors, some of whom represent all that is delicate and nearly perfect in skill and workmanship. I could point out several such occupants of space which others may have vainly longed for, and I feel confident that neither the Medical Director of the Exposition nor any other medical authority was consulted in the matter of their admission. In dwelling on the characteristics of the foreign exhibits in previous letters, I was not so much embarrassed by their numerical richness as I am now, when I find the ground so completely covered by American exhibitors, vieing with each other in honorable competition in every possible field of art and science in which the physician may be interested. With so many hundreds represented here, I cannot do more than briefly glance at a few, and to none can I give more than a passing notice, wholly disproportioned in many cases to the beauty, excellence, or grandeur of the exhibit. Nor can I separate the absolutely beautiful from the intrinsically useful, for, as in the case of the manufacturers of chemicals and drugs, who have piled up mountains of expensive salts of alkaloids which dazzle the eye with their magnificent crystals and geometrical shapeliness, the qualities of utility and attractiveness seem to be harmoniously and suggestively blended.

In the department of chemical and pharmaceutical products, to which I will first allude, the United States is singularly demonstrative. It is but a step across from the domains of his Majesty, the Emperor of Germany, to the contiguous exhibit of our own republic, and the progress of this country in the refinements of the chemical art is almost the first feature that arrests the eye of the visitor. Such a display as that which Powers & Weightman, and Rosengarten & Sons, of Philadelphia, and others, here offer, was scarcely possible from any foreign contributors, as the delicate, fragile blocks and crystals would have suffered a fatal martyrdom at the hands of even exceptionally tender and scrupulous handlers of merchandise *en route*. The exhibit of Powers & Weightman is certainly surprising in voluminousness, and costly in its richness, as it is, of course, excellent in quality. A mass of sulphate of quinia that weighs 1,003 ounces, morphia blocks whose ounces are also numbered by the hundreds, sulphate of codeia and of cinchonidia and quinidia weighed by pounds, caffeine representing in an imposing crystallized mass three-fourths of a ton of coffee;—these are only a few of the grander portions of an exhibit made up of the handsomest and most attractive drugs and chemicals, as to color and crystalline form, that it is possible to conceive. Not less important is the display of chemical and pharmaceutical products by Rosengarten & Sons, of Philadelphia, particularly of the alkaloids of cinchona and opium. The barks represented are numerous, and some of the rarer salts of quinia, as the tannate and hypophosphite, are especially interesting. The salts of manganese present a beautiful appearance, and the large, though by no means handsome, mass of opium is well worthy of careful inspection. In the same department we may also notice particularly the exhibit of carbolic acid, citrate of bismuth and of iron and bismuth, propylamin and its compounds, the various preparations of iron in scales, etc., by Billings, Clapp & Co., of Boston. Over sixty specimens are handsomely displayed, and the exhibit is highly creditable, not only to Boston, but to New England. Charles T. White & Co., of New York, also make an attractive exhibit of general chemicals, giving prominence to morphia, quinia and its valerianate and strychnia.

The manufacturing pharmacists, who are closely identified with their neighbors already referred to in business relations, are intimately associated with them also in location at the Exposition, being participants with them in catering to the successful instruction and interest of hundreds and thousands of visitors who linger long in this remarkable department. Wm. R. Warner & Co., of Philadelphia, who had already received awards at many of the expositions at home and abroad, make a fine display of sugar-coated pills, fluid extracts, elixirs, artificial fruit essences, and the general products of a pharmaceutical laboratory. A figure of the goddess of Health revolves above this handsome and extensive exhibit of pharmaceutical excellence, as if to indicate, what may not be at all improbable, that a return to health may frequently be hoped for from recourse to articles of the materia medica so well prepared for popular use and for dispensation by the judicious practitioner. Phosphorus seems to occupy a prominent place here, the element being declared to be thoroughly diffused and subdivided, and perfectly protected from oxidation. Bullock and Crenshaw, of Philadelphia, also make a fine display of a most reliable collection of similar pharmaceutical preparations and chemical apparatus. They were among the very earliest to practise sugar-coating of pills in this country, and their list includes an immense number of officinal and other formulæ. We naturally find the contest between the sugar-coaters, the gelatine-coaters, and the compressors of pills carried into the very Exposition itself. It makes but little difference to whom the award may be given by the judges of this department; the discussion of the merits of each form of pill will grow warmer from the jealousies of the chemists and pharmacists who advocate it. Medical men will doubtless be incited to a closer scrutiny of their claims by the agitation, and will weigh the arguments of each, especially of those which have received the commendation of the judges of award. Frederick Stearns, of Detroit, has endeavored in his exhibit of the products of pharmacy, such as pills, elixirs, fluid extracts, spices, troches, effervescing granules, etc., to illustrate the progress made towards rendering remedies pleasant to the eye and agreeable to the taste. His cases are said to represent nearly ten thousand items, and his sugar-coated pills are described as being made by building up in steam-warmed revolving pans, first the pill itself

upon a minute granule of cane sugar, and afterwards coating the same with pure sugar, using no varnish—softness, porosity, and solubility being aimed at, rather than perfection of sphericity or whiteness. McKesson and Robbins, of New York, are, in addition to being manufacturers of fluid extracts and other preparations, well-known as the advocates of gelatine-coating for pills, and of pills so covered they make a very interesting exhibit at the Exposition. It is not our province or purpose to enter into this controversy, but simply to direct attention to this coating as another popular form of administration. Who shall decide until pharmacists themselves agree? A smaller amount of excipient is said to be required in this process of gelatinizing the granule, a fact that is in some respects a recommendation, even if it should, as it doubtless does, give the homœopathic practitioner frequent opportunities of employing regular medical preparations, for which the doctrine of infinitesimal doses will claim all the credit. Another advocate of gelatine may be found in Keasbey and Mattison, of Philadelphia, who also make a special display of granular effervescent preparations—tasteless quinia, being quinia disguised by admixture with compound tincture of eucalyptus; citrate of caffeine, etc.

Outside of the domain of general chemical or pharmaceutical manufactures, may be mentioned several interesting allied products of general interest to the medical man. Perhaps there are none more so than the exhibition of the mode in which the natural mineral waters of Saratoga can be transported, in all their original purity and freshness, to a distance, as to Philadelphia—a fact of which the writer can speak from personal knowledge. Here is an exhibit by A. B. Lawrence & Co., of Saratoga, of Union and Excelsior Spring water, on draught, which have been barrelled by hydrostatic pressure, the water being conveyed from the spring, at a depth of twelve feet below its overflow, to the barrelling vault, through a block-tin pipe into block-tin-lined reservoirs, the gas being thus prevented from escaping. The mechanism inside the reservoir consists of two block-tin tubes, one of which, a long tube, leads from top end to bottom of the reservoir, and the other, a very short tube, also inserted and firmly secured at top end, merely extending through and attached to the block-tin lining. The atmospheric air is driven out through the short tube, and as soon as the reservoir is filled with water, both tubes are closed perfectly with screw caps. This is undoubtedly a much more satisfactory method than that sometimes adopted by druggists, who honestly dispense the other natural waters of Saratoga in the best way at their command, infusing into them the sparkling vitality, which they do not usually possess after transportation, by a few turns of the carbonic acid spigot. I say this much of the honest apothecary, because I know that artificial Congress and other waters are often palmed off on the unsuspecting for the natural article.

Aschenbach & Miller, of Philadelphia, in their exhibit point out the success of chemistry in imitating the flavors of fruits, and, although this would not at first sight appear to be a subject in which physicians are particularly interested, it may be a matter of some surprise to many of them to learn how perfectly raspberry, pineapple, and other flavors are imitated by compounds made from acetate, butyrate, and valerianate of amyl, all derived from the disgusting fusel oil or amylic alcohol; also from acetate, butyrate, and formate of ethyl, the butyric ether being obtained by subjecting grape-sugar to the lactic acid fermentation, old cheese or putrefying meat being used as a ferment.

Among the derivatives from petroleum which have come into use during the few years past, has been a substance called cosmoline, manufactured by E. F. Houghton & Co., of Philadelphia, and said to be a heavy, paraffinous, oleaginous hydro-carbon, purified and concentrated, and used externally in various forms of camphorated, carbolized, and other preparations, all of which are exhibited at the Exposition.

I offer these merely as samples of the kinds of exhibits to be seen in this department, with no intention to slight numerous other manufacturers and dealers, whose displays may be equally meritorious.

The collection of surgical instruments constitutes a very attractive feature of the American medical exhibit. Undoubtedly the finest displays are those made by Geo. Tiemann & Co. (Stohlmann and Pfarre), of New York, Codman & Shurtleff, of Boston, and J. H. Gemrig, of Philadelphia. The Boston firm has been allotted the greatest amount of space, from the fact that their exhibit includes not only a large collection of surgical instruments, but also of dental and other appliances and machinery. These three firms undoubtedly represent all that is novel and effective in the mechanical applications of the instrument-maker's art to the assistance of the surgeon, and in the perfection of design, ingenuity, and finish in this direction. I will take as an illustration of novelties in this useful department the exhibit of the centrally situated member of this trio, the old-established house of Tiemann & Co. Their Centennial case, of rosewood, and valued at eleven hundred dollars, contains the instruments for almost every important operation, and has nine trays or drawers, which can be removed and carried as separate cases by enclosing each in its appropriate leather pouch, each tray holding the instruments for a special operation, as amputations, for the eye, lithotomy, etc. We notice, also, a portable army pocket-case, to be carried like a cartridge-box by a shoulder-strap, from which, for hospital or office use, it can be readily removed by a slide; also an aspirator pump of celluloid, on a new model, which may be used for the stomach and for injecting purposes, one end exhausting, and the other expelling the fluid; all the new stricture dilators and cutters; a new rotating osteotome; fenestrated embryotomy forceps, and œsophagus forceps, which open with wide jaws, without increasing the size of the stem; all new forms of parallel dilators for forcible dilatation of the uterus; uterine or tonsil aspirator, which incises and immediately exhausts the blood or pus; water-lined trusses; painless hypodermic syringes; automatic ligatures a clamp needle which brings the edges together and yields a little to the swelling; a new sphygmograph with a laterally moving indicator; a new form of pocket spirometer; double curved self-registering thermometer; a new flexible chain saw, made up of steel beads, and capable of motion in every direction. These are specimens taken at random from a brief inspection of a case full of novelties, and are merely mentioned as an indication of the improvements constantly going on in the department of surgical manufactures. Horatio G. Kern, of Philadelphia, in an interesting exhibit of surgical and other instruments, claims peculiar merit for his dental extracting forceps, from the adaptability of such forceps to the particular tooth it is intended to extract. seventy-five varieties of the instrument being manufactured, without a duplicate in form.

Mr. T. Mellroy, of New York, exhibits several very ingenious and complete invalid and fracture bedsteads, surgical operating tables and chairs, and various requirements for the comfort of invalids. These

are most of them so well known, from their employment in the army and navy medical services, in civil hospitals and private practice, that it seems almost unnecessary to describe them. Such appliances, as the inventor states, are not only for the comfort of the sick and afflicted, but for the ease of the nurse and the convenience of the doctor. The collection includes an invalid and elevating bedstead, a hospital bed, a fracture extension appliance, a surgical operating table for hospitals, an oculist operating chair, a speculum or operating chair, and a recently invented revolving post-mortem or anatomical table, with scales weighing from a quarter ounce to 600 pounds, etc., proper attention being paid to its interior ventilation, communication with the sewer, etc.

R. J. D.

THE TREATMENT OF ASTHMA.

To the Editor of The Medical Record.

Sir:—The letter of Dr. Beard, in the last issue of the Medical Record, is very strange if meant as a reply to my communication (in No. 310, Medical Record). He first makes some erroneous statements, unjustly ascribing them to me, and then refutes them himself. This may be an easy method of convincing those unacquainted with the subject under consideration, but it is certainly illogical, to say the least. I distinctly stated in my communication to you, Mr. Editor, that I did not wish to enter into a discussion as to the priority of the nerve-theory of asthma or its treatment by galvanism; I merely mentioned the facts that in 1870 I read a paper on asthma, and published it in my *Galvano-Therapeutics*, where (long before Dr. Beard) the nerve-theory of asthma was clearly pointed out, and my methods of treating it by the galvanic current were given in detail, with illustrations of cases treated by me according to these methods. These statements I still maintain, because they are perfectly correct, leaving Dr. Beard responsible for his erroneous statements.

Very truly yours,
Wm. B. Neftel.

AMMONIUM BROMIDE IN HAY-FEVER.

To the Editor of the Medical Record.

Dear Sir:—I desire to call the attention of the profession to the local use of ammonium bromide as a means of relief for the distressing symptoms of summer or autumnal catarrh—hay-fever, so called.

It is well known that the bromides, when administered internally for a number of days, produce anæsthesia of the pharyngeal mucous membrane; and some practitioners (myself among the number) have used a strong solution of one of the bromides as a gargle, in cases of irritable throat, with excellent results. I have also employed ammonium bromide as a vaginal injection in a case of irritable bladder, with immediate good effect.

Reasoning from the above facts, I was led last summer to suggest to my friend, Mr. S. A. Solomons, a student of medicine, to make a trial in his own person of a solution of ammonium bromide as a wash for the nasal passages and as a gargle, to relieve his hay-fever. He tried the experiment, and obtained marked relief, infinitely more than he had obtained from any other means. Mr. Solomons also prescribed the solution (to be snuffed up into the nostrils and used as a gargle) for a lady who had been a martyr to the disease for many years. In a short time this patient wrote, saying that the bromide had almost entirely relieved her of the irritation attendant upon the disease, and expressing her great gratitude for the suggestion.

I would ask physicians to make an extended trial of this medicine, as follows:

1. A solution of ammonium bromide, ʒ j. or ʒ ij. in water ℥ j., to be used as a gargle frequently.

2. A solution of the same salt in the proportion of 10 or 30 grs. to water ℥ j. to be inhaled into the nostrils—not forced in with a syringe or douche apparatus.

It is very probable that by means of a spray-producing apparatus these solutions may be better applied to the larynx, throat, posterior and anterior nares.

Yours very truly,
E. C. Seguin, M.D.

P.S.—The suggestion is made without any reference to the parasitic or neurotic theories of the disease.

PROF. BILLROTH AND HIS OPERATIONS.

To the Editor of The Medical Record.

Sir:—Without any invidious comparison, it may fairly be said that there is no operating theatre in Vienna so popular as Professor Billroth's. The cause of this is not wholly unconnected with the qualities of the principal performer. A profound pathologist, an accurate anatomist, an operator bold to the verge of rashness, an easy conversational lecturer, an accomplished linguist, a good blackboard draughtsman, are qualities not every day to be found combined in one who, during the most severe and tedious operations, preserves an amiability and unpretentiousness which makes his presence a companionship to the youngest assistant. Nor does one often find the strength and endurance of a blacksmith uniting these qualities on the one hand to a distinguished social reputation as a composer and pianist on the other. A combination of qualities like this, in one so favorably circumstanced, could hardly fail in achieving the popularity and success which Prof. Billroth has accomplished. In the theatre Prof. Billroth is attended by nine assistants, all of whom he encourages to operate there occasionally, and thus secures for them a sort of training not afforded in any other operating theatre with which I am acquainted. All the apparatus is according to Lister—carbolized gauze, carbolized oil-silk, carbolized caoutchouc, salicylic charpie, salicylic jute, etc.—most of them of the exquisite Schaffhausen manufacture, being ready in proper order. That pest of surgeons, ready-made (non-) adhesive plaster, is here unknown, the emplastrum diachylon being always freshly spread on linen cloth as required for use, and is always soft, pliant, and thoroughly adhesive. The ligatures on hand are carbolized catgut, fine silk, and fine flax—the two latter lying in a carbolic solution. The flax, though fine, is very strong when wet, and is more generally used both for ligatures and sutures. The instruments to be used are laid out in a carbolic solution of a strength of three per cent., contained in shallow porcelain trays, in which also, before commencing to operate, the fingers of the operator are dipped, as also from time to time during the operation. Billroth has a peculiar penchant for bull dog forceps (with slide). Instead of waiting to tie arteries as he proceeds, they are instantly seized and left in the care of the forceps—as many as twelve of them have I seen hanging like leeches from a wound—until, a convenient stage of the operation being reached,

they were, as far as necessary, relieved by ligatures. This plan greatly facilitates despatch, and is particularly convenient and serviceable in the extirpation of large fibrous or carcinomatous tumors. In the closure of wounds, Billroth uses a great many sutures, making coaptation as perfect as possible, but uses drainage tubes very freely. From a wound by no means large, following extirpation of the rectum, I have seen as many as eleven drainage tubes projecting. In the Lister dressing (which, after unsuccessful experiments with boracic solutions, has been reinstated with increased care), an improvement in the way of economy has been introduced. For the caoutchouc, or oil-skin, previously placed between the sixth and seventh layers of the Schaffhausen carbolized gauze, paper has been substituted, so prepared in a mixture of linseed oil, white wax, and litharge, as to answer the same purpose. In such a large hospital a great saving is thus accomplished.

The *Anæsthetic* used by Billroth is not unlike that used by Dittel, consisting of three (3) of chloroform, one (1) of ether, and one (1) of alcohol. The special advantages claimed for this mixture is that it rarely produces cramp or vomiting. Upon the whole, I think its claims are sustained. However, vomiting not only does occur with it, but it has taken place precisely when it was most likely to prove disastrous.

The *Inhaler* in use here and generally throughout Vienna is a very simple affair. A scoop of wire-work, large enough to cover the nose and mouth, is covered with a single cap of flannel, which is tightened around the frame by gusset and tape. The anæsthetic is poured upon the outside only, and in drops, the bottle always having a stopper-tube attachment. The patient can breathe either through or under this inhaler, as may be desired. It is light, handy, cheap, and for safety, simplicity, and economy, this method of administration is highly to be commended.

Esmarch's Method, when practicable, is never omitted; the elastic tube is entirely discarded—an elastic band, simply a little narrower than that used for the preliminary compression, being substituted for it. There is a suspicion, however, that in addition to the temporary paralysis sometimes caused by this method, it has a tendency also to interfere with prompt primary union. From a multitude of cases and facts observed, the following may be not devoid of interest:

Lymphoma Maligna has in three successive cases been recently treated successfully. In the last case, a man thirty years of age, a very large number of the superficial lymphatics were exceedingly enlarged. The treatment was Fowler's Solution, five drops, gradually increased to twenty, internally daily. Also, into the body of each tumor, by turns, an injection of one drop occasionally, several of them being injected every day. The tumors at first were quite stubborn, but after beginning to be soft and movable, they progressed rapidly to disappearance.

Atheroma of the Lower Jaw—in point of location so rare, Billroth had never before seen it. The patient was a woman, twenty-five years old, and the tumor, which was situated just beneath the bicuspids and first molar on the right side, was about the size of a walnut. It had been growing about two years, but had been painful about two months only. At first sight it might have been taken for epulis or dentigenous cyst; but on proceeding to operate, the tumor was found to consist of a cheesy, calcareous mass. The surface beneath, after being well scraped to the depth of about (3) three millimetres, looked healthy, and the wound healed without further trouble.

Obliteration of the Vena Azygos.—In this case, which was more interesting than instructive, a man aged fifty had great œdema of the face and neck, and enormous distention of the superficial veins of the thorax, but with no evident cause. The diagnosis made at the time was occlusion of the superior vena cava, by a substernal tumor, and a preparation in the museum, with which this case was supposed exactly to correspond, was shown in illustration of the patient's condition. Two weeks afterwards the patient died in the wards of Prof. Bamberg, from suffocation. It was then found that the obliteration was of the vena azygos, and the cause of it a strumous tumor of the thyroid gland, which had more recently become carcinomatous. A full description of the pathological condition and collateral circulation will shortly be published by Dr. Chiari, who is making a careful preparation of the subject, which will probably be sent to the next Paris Exhibition.

Prolonged Interval in Carcinomæ Linguæ. — A healthy-looking man, æt. fifty-five, presented himself for the extirpation of a small epithelioma, which for two or three months had been growing on the left side of the tongue. On the right side of the tongue was a healthy cicatrix, marking the site of an extirpation of an epithelioma fifteen years ago by Schuh, Billroth's predecessor. To Billroth, who is a relentless extirpator of cancer, this was a gratifying incident.

Subcutaneous Osteotomy.—Not only in club-foot, but in rachitic deformities of the legs, I have never seen a case present itself here, however bad, but its treatment has been undertaken, the courage displayed and the results obtained being very interesting to witness. One patient, a young man, eighteen years old, I saw, upon whom subcutaneous osteotomy of both tibiæ had been performed only two years before for double valgus, and in whose gait there remained no trace of apparent deformity. This operation Billroth practises only when simple manual force is insufficient. In its performance he never uses the saw. An incision is made as small as will admit a small chisel, and then, with this and a hammer, the tibia is divided, if necessary, completely; but if not, only so far as will enable the operator to use manual force most effectively. All the straightening gained is immediately secured and maintained by plaster-of-Paris dressing. In no case, even when the treatment has been most daring, have I failed to see the results more than justify the measure.

Extirpation of the Rectum.—Though somewhat singular, this operation is with Billroth the rule rather than the exception for carcinoma of this region. Almost the only limitation he makes is that all the parts diseased are within easy reach of the index finger. I think, however, I have seen this limitation decidedly overstepped in one operation, in which en route the membranous urethra and prostate were as cleanly dissected as if for a preparation. After the extirpation the cut end of the rectum is brought down, and as far as possible stitched to the integumental margin of the wound. This, however, generally breaks away and retracts, leaving a large excavation to be filled in by granulation. The important matter of keeping this excavation clean is accomplished only by at first the free use of drainage tubes, and afterwards by diligent irrigation. Of the six cases under my observation, the youngest of which was a female of twenty-two, four made a good recovery, and did not suffer from involuntary discharge of fæces. Of ten previous cases, Prof. Billroth tells me four died, and the rest did well—a success as regards the primary results which is certainly encouraging in this field of surgery.

Hysterotomy and Ovariotomy.—In these operations

Prof. Billroth always uses the clamp; for ligatures, if necessary, usually carbolized catgut; and for sutures, carbolized fine silk; he leaves generally two or three drainage tubes in the wound, and, as may be supposed, finishes with the Lister dressing. In one case of hysterotomy which did well—in a patient æt. twenty-five—for about two months after the operation a fistula continued in the abdominal wound communicating with the vagina, the lips of the fistula being vaginal mucous membrane. Under occasional application of nitrate of silver, it closed without trouble. In another case of hysterotomy, in which, besides other bad symptoms, meteorism was very troublesome, intestinal puncture wss resorted to; but it availed nothing, and the patient died the following day. At the post-mortem the intestine was found to be rendered impassable; a Meckel's diverticulum about six inches in length encircled it, and this, with the advent of inflammation, had caused strangulation. The puncture was found to have been below the point of strangulation. Only a few days afterwards similar symptoms occurred, with fæcal vomiting, in another case, and, warned by the recent experience, Billroth for the first time, as a sequel to ovariotomy, performed enterotomy. The bowel was thus emptied and kept so, and vomiting did not recur; but the next day the patient died. The cause of the strangulation was deemed to be twisting of the bowel and adhesive inflammation of a portion of mesentery.

In two cases in which the clamp could not be used, the pedicle was secured by carbolized silk ligatures, which were cut off short. They were both exceptionally bad cases, and both died. In one of them, in which several ligatures had been used, and in which death occurred on the eleventh day, on examination I found none of the ligatures coated by lymph or fibrine.

Having by the kindness of Prof. Billroth been present at all his operations of this class for the past four months, both private and public, I have been principally impressed with the fact that amongst the private cases there has not been one death—these having occurred exclusively in the general hospital. The youngest cases have been respectively seventeen and twenty-one, and these, from first to last, progressed more rapidly than any others on the list. When the number of cases he wishes first to complete is reached, Prof. Billroth will publish his results.

B. Howard, M.D.

Vienna, October 4, 1876.

IS ALCOHOL A FOOD?

To the Editor of The Medical Record.

Dear Sir:—In a previous number of The Record, Dr. Mays seems to desire to support the theory that alcohol is a food. The question presents itself, What is a food? that which supports life, or that which replenishes tissue?

Does alcohol support life? Does it contain those elements which replenish the tissues of the body, as they are day by day worn out and cast off?

Organic chemistry teaches that all tissue material supplies contain nitrogen as an essential part; that all force-giving foods are hydrocarbons. Alcohol contains no nitrogen; hence it cannot be a tissue food. Is it then a force-supplying food? No.

In the researches of Dr. Anstie, assisted by Dr. Dupré, the results of his experiments were unmistakable in their bearing on the question.

Hydrocarbons produce force by oxidation. Alcohol is a hydrocarbon, and, if consumed in the body, must produce heat, in order to rank among the heat forming foods. Does alcohol cause an increase of animal heat? The experiments of Dr. Benjamin W. Richardson,* of Edinburgh, on this question, go to prove that, instead of producing animal heat, it diminishes the heat in the body. He divides the progressive changes of animal function from alcohol into four stages:

1st. Stage of excitement, with relaxation and injection of the blood-vessels of the minute circulation with which we have become conversant.

2d. Stage of excitement, with muscular inability and deficient automatic control.

3d. Stage of rambling, incoherent, emotional excitement, with loss of voluntary muscular power, and ending in helpless unconsciousness.

4th, and final stage, where the heart begins to fail, and in which death, in extreme instances of intoxication, closes the scene.

In the first stage the temperature may rise to one-half degree Fahr. in man. In the second stage the heat comes down to its natural standard, and then declines below what is natural. During the third stage the fall in temperature rapidly increases, and, as the fourth stage is reached, it approaches a point that is actually dangerous. There is, also, during this stage, profound coma, or sleep, and, while this lasts, the temperature remains reduced. And here we have a diagnostic point between the sleep of apoplexy and the sleep of drunkenness, for in apoplexy the temperature remains normal.

These researches, although differing in results from Drs. Anstie and Dupré, would, I doubt not, have been reached by Dr. A., had not his useful life been cut short at the time it was.

Edw. H. Stimson, M.D.

Orange, Mass., Oct. 9, 1876.

BLEPHARITIS CILIARIS AND ERRORS OF REFRACTION.

To the Editor of The Medical Record.

Sir:—I am convinced, by observations made in two hundred and eighty-five cases of errors in the refraction and accommodation of the eye which I have made record of the past ten years, that the disease known as blepharitis ciliaris, or oph. tarsi, is usually accompanied with, and often wholly caused by, these errors.

Several test cases were made of patients, by giving them no other treatment than properly-fitted lenses to correct the errors. Some were hypermetropic, and others astigmatic, or both combined, and the result seems to warrant me in calling the attention of the profession to the subject.

Heretofore reliance has been placed upon local applications and digestive tonics, to the neglect of what, I am confident, is a valuable aid.

Not only have I found the local lesions cured by properly-fitted lenses, but the disturbances of digestion have also disappeared.

A case illustrative. U. B., young man from Vermont, applied for treatment, with the following symptoms: eyelids swollen; borders everted, and presenting at points pustules and accumulated crusts; eyelashes partially lost; tarsal conjunctiva congested. There was also the usual complaint of neuralgic pain about the eyes which accompanies hypermetropia, and also symptoms of indigestion—a coated tongue, eructations, unpleasant dreams, etc.

* Cantor Lectures "On Alcohol," by Dr. B. W. Richardson. Published by J. N. Stearns, Agent 58 Reade street, New York.

Examination revealed ametropia, requiring a convex lens $+\frac{1}{14}$, to correct the error of refraction.

The manifest hypermetropia was $+\frac{1}{20}$. Spectacles $+\frac{1}{20}$ were advised, with recommendation to change to $+\frac{1}{18}$, $+\frac{1}{16}$, $+\frac{1}{14}$, if tolerated.

Six months later he was well, but had not changed his first glasses. A year or more afterwards he reported that his eyes had not troubled him since three weeks after he first used his glasses.

Second case. C. D.; young lady. She had been under severe treatment for neuralgia and inflammation of the eyes, oph. tarsi, etc. Five months in a hospital, and a course of mercury, made up a part of her history.

Examination revealed astigmatism. This was corrected by proper lenses, and in a very few days she was fully relieved of all trouble.

Many other analogous cases might be selected from my record; but some of them were otherwise aided by eye salves to soothe excoriated surfaces, or, perhaps, had some constitutional treatment for complicating ailments.

The above two cases typify the others on the list, although many of them were less marked in character.

SPRINGFIELD, MASS., Oct. 21, 1876.

OIL OF CORN AS A REMEDY FOR ECZEMA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Nearly one year ago a young man, resident of this city, who had long suffered severely with eczema of the fingers and hands, was induced to try the oil of corn for their relief, and was so much benefited by the first application that he continued its use, and very soon had the satisfaction of a more complete freedom from the affection than he had experienced for several years.

My observations of the action of this substance in his case and others since have persuaded me that it is a valuable medicine for the treatment of this very troublesome and obstinate disease.

The first case in which it was employed was a severe one; all of the fingers were involved in their whole circumference and the disease was deep in its action, so much so as to involve the matrix and loosen the nail on some of the fingers.

He had, on the prescriptions of physicians and others, employed remedies, usual and unusual, local and constitutional, but, in his estimation, none ever did him so much good as the oil of corn. With its use his hands soon became well, and have so remained since.

The oil thus far has been obtained in the following simple manner: A handful of grains of dry indian-corn (*zea mays;* the yellow variety has been chosen, though the white may be equally good) is placed on the blade of an ax, and a good-sized piece of iron, brought to a high degree of heat, pressed firmly on it.

The process is a slow and laborious one, as but a few drops are obtained from each handful of corn, and is caught as it flows off the edge of the ax.

On cooling it possesses near the consistence of liquid pitch and is equally black from the charring of the corn. It has a pungent odor, and the burning sensation is quite severe for a few minutes after its first application. The objectionable coloring of the hands passes away in a few days after the applications are discontinued.

Application has been made to Messrs. Powers & Weightman, Philadelphia, who will probably soon be able to furnish the oil free from the black coloring.

CHAS. E. SLOCUM.

DEFIANCE, OHIO, Oct. 2, 1876.

THE UNIVERSITY OF MICHIGAN AND THE MICHIGAN STATE SOCIETY.

TO THE EDITOR OF THE MEDICAL RECORD.

DR. JOHN P. STODDARD'S communication in your issue of 12th Aug., in reply to one from Dr. Maclean, should certainly not have been permitted to go so long unchallenged, but for the knowledge that Dr. S. had been appealed to by a member of the Judicial Council who took pains to set him (Dr. S.) right as to the matter of fact at issue between Dr. Maclean and himself, and asked Dr. S. to withdraw the misstatements contained in his letter to you. Having now waited quite long enough and in vain, for his explanation and recantation, I feel called upon to trouble you with a few words in reply to him.

As the charges under which the Michigan State Society is at present arraigned before the Judicial Council of the American Medical Association were preferred by myself, I presume Dr. S. will concede my right to speak authoritatively with regard to their aim and scope.

My colleague, Dr. Maclean, was quite correct in stating, as he did in his letter to you, that "The Michigan State Medical Society is even now under charges before the Judicial Council." These charges are based on the fact that this Society has, through a committee duly instructed for the purpose, met and consulted with the representatives of irregular systems of medicine for the avowed purpose of obtaining from the Legislature of the State an act by which *every graduate* from *regular schools*, aspiring to practise *rational medicine* in this State, would be required to pass an Examining Board, the majority of whose members were to be homœopaths and eclectics. And this committee, having so met and consulted, reported their conduct, which was approved by the Society, and a committee continued with instructions to persevere in the effort to obtain this law.

As Dr. Stoddard took an active part in the attempt to create this mixed Board of Examiners, his criticism of the present condition of affairs in the Medical Department of this University seems to me very unjust, and his advice to its much abused faculty very ungenerous.

If some one should falsely accuse Dr. Stoddard of a crime, and employ witnesses to destroy his character, and these witnesses could easily be impeached, would he have such regard for the "dignity" of silence as to leave his defence to the chance impulse of a friend, or would he defend himself?

The Michigan State Society, packed by the friends of private schools, sought to destroy the reputation of the University school by a resolution declaring its position to be inconsistent with the interest and honor of the profession.

The State Society must now choose whether it will confess this resolution to be an error, or be convicted of *intentionally* compromising the interest and honor of the profession in this State. Since, if the "existing situation of the Medical Department" of the University is inconsistent with professional honor and dignity, its own conduct must be still more so.

Very truly yours,

GEO. E. FROTHINGHAM.

ANN ARBOR, Oct. 23, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Oct. 29th to Nov. 4th, 1876.

Edwards, L. A., Surgeon. Leave of absence further extended six months on surgeon's certificate of disability. S. O. 230, A. G. O., Nov. 3, 1876.

Jaquett, G. P., Asst. Surgeon. Assigned to duty at Edgefield, S. C. S. O. 157, Department of the South, Oct. 25, 1876.

Brown, H. E., Asst. Surgeon. Relieved from duty in Department of the South, and to report in person to Commanding General Mil. Div. of the Atlantic for assignment. S. O. 230, A. G. O., Nov. 3, 1876.

Styer, Chas., Asst. Surgeon. Leave of absence extended twenty-three days. S. O. 213, Div. of the Atlantic, Nov. 1, 1876.

Ainsworth, F. C., Asst. Surgeon. To report in person to the Commanding Officer Depart. of Arizona, for assignment to duty. S. O. 230, C. S., A. G. O.

New Instruments.

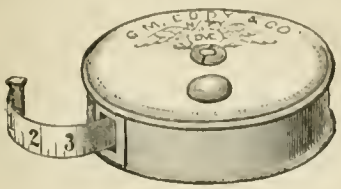
THE PLIABLE PESSARY.

The pliable ring pessary constructed by F. G. Otto & Son has some advantages over those of the hard rubber sort, which commend themselves to the attention of gynecologists. It combines softness, firmness, and smoothness, with easy and perfect flexibility on any desired plane; in fact, it can be twisted or doubled in any direction required. As will be seen by the accompanying sectional drawing, there is an explanation for this not only in the materials used, but in the methods of their adaptation to the principle involved.

The basis is a long, slender, round piece of whalebone bent up on itself many times to form a compound ring, enveloping which is a ring of spiral wire, and over the whole an envelope of rubber.

STEEL POCKET MEASURE.

G. M. Eddy & Co., of Brooklyn, N. Y., have lately manufactured a steel pocket measure which we think will prove useful to physicians. On one side of the steel ribbon the measurements are marked by English inches and on the other by French metres. The advantages of such arrangement are quite obvious to



those who may wish to become practically familiar with the decimal system. Its mechanical construction is such that it is not liable to get out of order, while its sure and easy method of working is of itself a recommendation.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending November 4, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Oct. 28	0	11	28	1	19	39	2
Nov. 4	0	17	31	1	17	40	2

Phthisis and the Babas in Servia.—When the efficacy of ordinary simples is lost, the *babas* have recourse to cabalistic science. For phthisis they take three apples, which grew on the same branch, to represent the Trinity. A knife is driven into one of these and left there twenty-four hours, and then the apple is given to the patient to eat. In desperate cases the patient is stretched on his belly on the ground, and the baba strews salt around him and then strides over him several times from right to left. She mutters at the same time formulas that are reputed to be sovereign, and makes mysterious signs.

Devotion to Science.—An American lady, by the name of Smith, proposes to bequeath her body to the Royal College of Surgeons, for anatomical purposes, after which portions of said body are to be distributed among such of her friends as may desire them.

Yellow Fever has almost disappeared in Savannah.

Honors to American Medical Men.—At a recent meeting of the Medical Society of London, Mr Wm. Adams, President, gave a detailed account of his visit to the International Medical Congress. He referred in very flattering terms to our progress in medical matters, to our medical colleges, hospitals, museums, and libraries. In speaking of American surgery, he said it was essentially the surgery of England, and, in the way of improvements in its practice, he mentioned the weight extension in fractures, giving the credit of its introduction to Drs. Gurdon Buck and H. G. Davis of this city. Before reading his address, he proposed as corresponding fellows to the Society, Professors Gross and Pancoast of Philadelphia, Professor Flint of New York, and J. K. Barnes, Surgeon-General of the United States Army.

Ventilation of the College of Physicians and Surgeons.—The ventilation in the Theatre of Anatomy of this college is so far beyond perfection that it is difficult to get out of reach of some lively current. This is particularly the case during the evening meetings of some of the medical societies.

Dr. Gurdon Buck, our distinguished townsman, has so far recovered from his recent illness as to be able to attend the hospitals and occasionally to operate. He has just published his work on Reparative Surgery; the cases detailed therein being profusely illustrated with cuts.

An Amputated and Mutilated Hand was found, a few days since, in a gutter in 26th street. It was evidently removed from a dissecting-room subject by some medical student who wished to create a sensation. It is to be hoped that the perpetrators of this piece of blackguardism will be apprehended and severely punished.

Dr. Frank H. Hamilton will hold a surgical clinic at Bellevue Hospital every Wednesday, at 2.30 P.M., during November and December.

Dr. Sayre's work on Orthopedic Surgery is to be translated into German and French.

The Mucous Membrane of the Stomach and Cerebral Lesions.—Softening and ulceration of the mucous membrane of the stomach are said by Brown-Séquard to follow injuries of the corpus striatum, the crura cerebri, or the spinal cord. On the other hand, hemorrhages generally follow injuries to that point in the pons where the middle crus cerebelli is inserted. Paralysis of vaso-motor nerves is not the cause, for there is contraction of the arteries and veins, and stasis in the capillaries which rupture.

Typhoid Fever in Paris.—When this epidemic was raging with severity last month, the readers of *La France Médicale* were furnished with a few editorial notes on the modern treatment of typhoid, especially that advocated by Liebermeister, and later by other German writers.

Attention was called to the fact that most clinical instructors recommend the use of the bath for moderating the temperature. Thus, when the fever heat has reached 107° Fahr., a bath of 68° Fahr. is to be given for from five to ten minutes, and repeated when the temperature again reached the same height.

In conjunction with the bath quinine is the great febrifuge. Twenty to twenty-five grains may be given at a dose, and even as much as forty grains within an hour. The reduction of temperature follows rapidly in most cases. It was by these two principal agents that Liebermeister reduced the ordinary percentage of mortality (27) to 8. His cases numbered 1,500. Within the past year the Germans have advocated the use of salicylic acid or the salicylate of soda, the former to be given in doses of from sixty to seventy grains. Reduction of temperature usually follows, it is said, in from three to four hours. When the salicylic acid is to be repeated, from thirty to fifty grains will usually be sufficient to promote the required reduction.

Typhoid Fever Caused by Impure Milk.—At a recent meeting of the St. Pancras (London) sanitary authorities, Dr. Stevenson reported that three cases of typhoid had occurred in well-appointed houses, situated in the Regent's Park sub-district. A searching investigation had revealed no defect in the construction of the houses, likely to explain the appearance of the malady, but he ascertained that all received their milk from one retailer. The farm supplying the milk was then inspected, and it was found that the cows had access to a pond containing crude sewage, a culvert opening into it directly, and bringing sewage from some twenty houses in the village. In the garden there was another pond of muddy water; there was also a shallow, fifteen-feet surface well, containing only a few inches of filthy water, and "from either of these sources came the water supply." The people at the farm alleged that they filtered the water, but the health officer actually saw some of the filthy water in a large milk can and also in two pails.

Thomas Laycock, the distinguished medical author, Professor of Practice of Medicine in the University of Edinburgh, and Physician to the Queen for Scotland, died Sept. 21st, in Edinburgh, aged 64 years.

Propagandism in French Hospitals.—The propagandist ardor of some of the Sisters of Charity in Paris hospitals is so pronounced as to raise the indignation of the municipal authorities.

Convalescent Home at Strassburg.—M. Ehrmann, a millionnaire of Strassburg, left a million of francs to the hospital of that city to found a convalescent home.

Butterine is the name of an artificial compound of animal fat which is sold in Glasgow, Scotland, for butter.

The Plague is said to have broken out in the Turkish army, necessitating the change of position every three days and the burning of infected tents.

The projected "City of Hygeia."—Our esteemed contemporary *The Medical Press and Circular*, does not believe that the sanitary city will be a success, but is willing to await the developments of a practical test. In regard to the project itself, it says: "We live in an age in which the experimental philosophy is being pushed to a degree of which even Bacon himself could have formed no conception. This will be really an experiment on a gigantic scale, and such as we should have expected to see projected by our American cousins rather than by our own less venturesome countrymen."

Journalistic Enterprise.—The *American Practitioner*, in a spicy editorial article on the International Medical Congress, concludes by saying:

"One reason for the marked success of the Congress was the admirably-constructed machinery; it worked perfectly. Those gentlemen in Philadelphia who had the devising and arranging of it, deserve the best professional thanks.

"Only one thing in the action of the Congress is deserving of adverse and severe criticism, and that was the resolution offered by Dr. Eve, forbidding the publication of any of its proceedings, papers, etc., in any medical journal. Dr. Eve's good nature allowed him to be imposed upon in this matter. The resolution, so it was privately whispered in Philadelphia, was offered in the interest of a medical journal whose editor had failed to have any reports prepared, when it was found other journals were having such reports in preparation. Just as soon as the matter was generally understood, there was a feeling that would have secured the reconsideration and repeal of the resolution, only it was thought best simply to let the matter pass in silence, and act as if no such resolution had ever been offered. The New York Medical Record has shown the absurdity and uselessness of this action, and it is about time that such nonsense should be stopped in intelligent medical bodies."

Original Communications.

A CONTRIBUTION TO THE STUDY OF NEURALGIA. AN INTRACTABLE CASE IN PRIVATE PRACTICE.

By E. P. HURD, M.D.,

NEWBURYPORT, MASS.

NEURALGIA, more amenable to treatment than most of the other neuroses, sometimes presents itself in a very obstinate and intractable form. The following case, occurring in private practice, illustrates the difficulties which sometimes attend the treatment of chronic and anomalous cases. It is of interest, 1st, on account of its inveteracy; 2d, on account of the violence of the pain-paroxysms; 3d, on account of the extraordinary doses of opiates and other anodynes required for the relief of the pain; 4th, as illustrative of the fact that trivial exciting causes, in a person of strongly neuralgic diathesis, are frequently sufficient to provoke an attack; 5th, as showing that neuralgia, like epilepsy, is often excited by unknown external or internal irritants, so that the *causa morbi* cannot always be foreseen and avoided; 6th, as showing that the cause is sometimes ascertainable, if not easily preventable; 7th, as showing that irritations of peripheral nerves, in neuralgia, may so exalt the excitability of certain ganglionic spinal centres as to seriously perturb all the nerves, sensory and motor, originating there—whence pain and spasm, radiating outwards, and manifested at a distance from the original neuralgic focus; 8th, as showing that pain and spasm, reflex effects just mentioned, may be so violent, so diffused, and so persistent—certain reflex vaso-motor disturbances also accompanying them—as to simulate the manifestations of spinal meningeal congestion, and lead to an erroneous diagnosis.

"Neuralgic pains are characterized by the suddenness with which they come on, and the suddenness with which they sometimes go away; by the total absence, in most cases, of heat and swelling, and often of tenderness, too, when they are external, and of febrile symptoms when they are internal, even though their intensity be extreme; by their apparent dependence, in numerous instances, on sudden changes of the weather; by their occurring chiefly in persons of a nervous temperament in whom the health is otherwise disordered."* Exemplifications of these particulars are furnished by the case I am about to report; a marked degree of tenderness, however, over the painful foci was seldom absent.

History.—The patient is a daughter of an influential gentleman of this city, whom I will call Richards—is of delicate organization, twenty-four years of age. At ten years of age an attack of measles resulted in otorrhœa and deafness. Three years later she had typhoid fever, which was followed by temporary paralysis. In 1869, an attack of dysentery added to the debility ensuing from the previous illness. Then came severe intercostal neuralgia. The attacks were frequent, and were attended with cramps of the pectoral and intercostal muscles, and when left to themselves ultimately subsided with free vomiting and exhaustion. (In fact vomiting generally ensued, whether anodyne remedies were administered or not.) The usual treatment by opiates, Indian hemp, and other narcotics was faithfully pursued. The record declares that opium failed to give much relief to the paroxysms, and that even hypodermics of morphia aggravated rather than benefited. A new remedy, the product of the guarana sorbilis, was just then coming into vogue. Dr. H. C. Perkins, the attending physician, had obtained a quantity from Brazil, and had generously furnished samples to his medical *confrères*. Some brilliant cures were wrought, and every form of neuralgia seemed to be controlled by the paullinia powders. In the case of Miss Richards, the good effects of the paullinia were especially marked. Twenty-grain doses of the powder caused speedy disappearance of the pain. Her general health improved. For four years there was almost complete immunity from pain. Last fall she was in better health than usual; appetite and digestion good; could walk and ride *ad libitum*. A visit to Boston was attended by exhaustion and a serious nervous breakdown. The following memoranda are from notes taken since my attendance:

Nov. 23, 1875.—*Present Condition of Patient.*—Miss R. is a short, fragile, undeveloped little body; weight about 75; light hair, blue eyes; thin and pale; quite deaf; teeth all decayed; digestive functions, menstruation, normal; regular but weak and compressible pulse, 120; no febrile action. An attack of spasmodic asthma. Prescribed bromide potas. with belladonna; stramonium cigarettes to be smoked. Relief followed in a few hours.

I remarked on this occasion the exceeding good health of the parents. Neither father nor mother are "nervous" people. The former has a chronic bronchial trouble and rheumatic proclivities, but, though past sixty, is quite vigorous.

Dec. 8.—An attack of pain in left shoulder. In bed, sitting posture, father supporting and making pressure on the painful shoulder—pressure affording some relief.

A full dose of paullinia was given, but without effect. It was twice repeated within an hour and a half, and failed. And here it would be proper to remark that paullinia has never since been of any benefit. I injected hypodermically ¼ gr. morph., without effect. Another hypodermic, repeated in an hour, failed. Subsequent inhalation of chloroform caused a lull, and after free vomiting, she fell asleep.

Jan. 13, 1876.—Was summoned at ten o'clock P.M. The pain had returned in the left shoulder. Patient sitting up in bed, writhing with pain. "O dear! O dear!" was the constant, pitiful cry. Pulse 130, extremities cold, countenance distressful; shoulder drawn up by a tetanoid contraction of scapular muscles. Sometimes a wave of pain would attack intercostals of left side, and the clonic muscular spasms could be seen and felt. Hyperæsthesia of left shoulder and scapular region, and tender spots along the cervical spine; the *points douloureux*, however, were not significant, nor were they those that Valleix describes when treating the neuralgic affections of these regions. Two hypodermics of morphia, fifteen minutes apart, ½ gr. each, served but to intensify the pain and spasm. Squibb's ether was administered for forty minutes without causing muscular relaxation, or relieving the pain. Chloroform finally brought rest, but no amount of this anæsthetic then or ever produced unconsciousness, if I except momentary lapses into sleep from which *a touch* was sufficient to arouse her.

* Allison's Outlines, as quoted by Watson. The same writer adds: "This cruel malady occurs most commonly in persons who exhibit in other respects the signs of an unsound or deranged or debilitated system . . . Sometimes it is connected with a disposition to rheumatic affections."

Jan. 14.—On making my morning visit. I found that there had been a return of pain during the night—this finally had given way to prolonged vomiting. There was hebetude and prostration; irritable stomach, muscular soreness, extreme hyperæsthesia of left shoulder, which was still drawn up and made to hug the neck. Here evidently was hyper-irritability of a very limited nerve tract. Was it in some peripheral (cutaneous) branches, and therefore probably of rheumatic origin (a quite tenable hypothesis), or in the posterior roots of some larger nerve trunk whose molecular disturbances were propagated centrically and excentrically? The latter hypothesis would very well explain the symptoms, and be quite in keeping with Anstie's theory that neuralgia is the result of atrophic or degenerative changes in the roots of sensory nerves.*

Adopting this view, it would seem likely that the rhomboid branch of the fifth cervical might be the nerve principally at fault, and that the irritation might start from a sensory root of that nerve. The pain would be referred to the peripheral terminal branches of the nerve, in accordance with a well-known physiological law. The molecular disturbance, when intense, would be propagated in various directions, along lines of least resistance, and hence the spasm, the intercostal pain, etc. After all, I have been led to prefer the theory that the irritation giving rise to such painful manifestations starts invariably from the periphery—certain cutaneous branches whose anatomical elements, of low vitality, are wont to be injuriously affected by atmospheric changes (dampness, chilliness); by the systemic blood containing a pabulum insufficiently elaborated, or an excess of urea, uric, lactic, etc.; by physical violence, as when severe pain has been brought on by handling the arm a little too roughly or by an unlucky hit on the shoulder.†

Reasons will be given further on in support of this opinion. It is easy to understand that an irritation proceeding from the surface can do all that an irritation of centric origin can do. Moreover, the condition of the posterior roots that Anstie describes has not been proved to be a common concomitant of neuralgia. Nor is it easy to see the connection between such atrophy and the intense pain characterizing neuralgia, especially when it is taken into account that *atrophies*, not only of nerve-trunks, but of large masses of nerve-trunks in the spinal cord and in the encephalon, have been found after death, and yet pain was not a prominent symptom during the life of individuals suffering these degenerative changes.*

The hyperæsthesia is *exalted polarity;* this hyperæsthesia *intensified* is pain.†

To return to my report. The irritable stomach was first quieted, then bromide potas., in one scruple doses, was prescribed, also the sub. carb. iron in half-teaspoonful doses ter die. Wine and brandy *ad lib.*

Jan. 15.—Another attack of pain. This time it was the right shoulder that was affected. The left shoulder, still fixed in its unnatural position. The same writhings and outcries as before. A hypodermic of atropia $\frac{1}{75}$ gr. was given. The paroxysm passed off in a few minutes. The pain returned in an hour, to be again controlled by the atropia.

Jan. 16.—Prostration, hebetude, muscular soreness, anorexia, deformity of left shoulder very marked. Atropia, $\frac{1}{100}$ gr., to be given night and morning. Pancreatic emulsion after each meal. Bromide potas. mixture to be dropped, and bromide camphor given instead. (This soon had to be omitted as not agreeing.) Bowels constipated, owing probably to the large quantity of sub. carb. iron that was taken. Elix. laxative administered. Quinine in two gr. doses, instead of the iron powder.

From this time to the 23d there was no attack of any severity. Appetite became good. Scraped beef given; also eggs, milk, cream, oysters, custards, etc. (Want of teeth compels great care in the preparation of the food.) Nocturnal restlessness subdued by chloral in 10 gr. doses. On the 19th there was a return of pain, owing to hurting the left shoulder in moving her. It was subdued by two doses of chloral. Atropia was discontinued, not seeming to do any good. The emulsion was also dropped, as interfering with appetite, and a little salad oil was given instead. The soreness, debility, and tetany continued.

Jan. 23*d*, 24*th*, 25*th*.—Two very severe attacks of pain in right shoulder and side. Pain ingravescent. Comes on with slight twinges, relieved by pressure over the seat of pain; then there is a steady ache—then the storm is at its height. She sits up now in bed, though previously unable to move unless helped; the body sways to-and-fro, there are groans and loud outcries. Pain now in the shoulder, now in the right side, now in the left, and now in the back. Pain a constant heavy *thud*, aggravated by lancinating *thrusts*. The description of Jaccoud is strikingly *à propos* of our patient's condition during the attack: "Indépendamment des secousses lancinantes du paroxysme, les malades éprouvent une douleur *fixe*, ou *diffuse*, profonde et contusive, qui n'est point comparable à la première par son intensité, et qui survit pendant un temps variable à la terminaison de l'accès proprement dit."‡

During these two attacks everything seemed to fail, till the pain wore itself out. Atropia failed, so did morphia, so chlorodyne (Sir Thomas Browne's preparation), given in half-teaspoonful doses. Chloroform inhalations gave only momentary relief, though fully half a pound was used. After an hour of almost continuous administration of this anæsthetic by inhalation, the patient was still conscious, and not wholly relieved of pain and spasm.

Jan. 26*th*.—I rubbed croton-oil liniment along the lower cervical and upper dorsal regions of the spine.

---

* Anstie on Neuralgia. Philad.: Lindsay & Blakiston.

† "The (peripheral) afferent nerves of individuals, who, though otherwise healthy, have lax tissues, are often unduly impressible."—Herbert Spencer's Prin. Psychology, p. 70, vol. i. The above gives us a hint as to the pathology of this case. The ultimate peripheral termination of sensory nerves is the naked axis cylinder. Hence the terminations of the nerves are more exposed to disturbances and irritants of all kinds than are the nerve-trunks, or the posterior roots. In persons of low vitality and lax tissues, an extraordinary amount of change may be produced in nerves and nerve-centres by irritants that are trivial. The nerve molecules easily tumble to pieces, the least shock producing disintegration, instead of that moderate isomeric transformation which is normal. In undergoing disintegration they liberate all their contained motion, and speedily the whole nerve and its central ganglia are thrown into commotion. There is now riot and disorder, as much as in an epileptic convulsion.

This explanation makes the neuralgic attack literally a species of prolonged explosion, the unstable protoplasm of the axis cylinder being the *powder*, and some local, constitutional or external irritant the *spark*. The indication for treatment is, of course, to fortify and harden the constitution by a suitable invigorating nutrient and tonic regimen. The nervous system will participate in the benefit thus derived. Hence alcoholics, quinine, arsenic, iron, fats, etc., might be expected to do good. A better and more enduring protoplasm is wanted. Unfortunately, it is often easier to tell what is wanted than to carry out the treatment necessary. Neuralgia, a disease of civilization, would undoubtedly be stamped out by a return to savagism.

* Erb, in Ziemssen's Cyclopædia. For examples, see Vulpian "Leçons sur la Physiologie Comparée du Syst. Nerv."

† Jaccoud, Pathologie Interne, Paris, 1875, vol. i. p. 481. "Une hyperæsthésie morbide élevée à la puissance de la douleur spontanée, constitue toutes les névralgies."

‡ Jaccoud, Op. cit., tome I., p. 486.

The following pill to be given three times a day: R Quevenne's iron, gr. ij.; Ext. Cannabis Ind., gr. ½. M. Ft. pil.

Jan. 27th.—A slight attack of intercostal pain was relieved by firm pressure with the hand. Pressure has often seemed to abort pain in the side and shoulder. (I except the sensitive left shoulder, which cannot be handled—it is a *noli me tangere.*)* Another proof that the pain is of peripheral origin; else how could pressure modify a painful consciousness in nerve filaments that do not themselves originate the morbid disturbance?

March 9th, evening.—There has not been any attack of any severity since Jan. 25th. Premonitions have been promptly attended to; chloral proving of great service as a preventive. Croton chloral has of late been given instead of the hydrate, as being more pleasant to take.† The effects seem to be identical with those of the hydrate.

Is the good result in any measure attributable to the croton oil pustulation on the back? Theoretically, one would expect benefit from severe counter-irritation in such cases.

March 9th, evening.—A very severe attack (intercostal). Croton chloral in repeated 5 gr. doses failed. ⅛th gr. atropia with 1 gr. morphia, subcutaneously, relieved after several hours' torture.

March 10th.—Pain in side and shoulder. Another hypodermic of morphia, modified by atropia; relief. Stomach irritable; vital functions all depressed. To live on milk, and discontinue all medication.

March 18th.—Another paroxysm, relieved as before. Patient looks pinched; is of leaden hue; pulse, 130; breath very offensive; in fact, all the secretions are depraved, a result probably of reflex vaso-motor disturbances, so often remarked in neuralgias. The perspiration after an attack often has a rank smell, and the urine is wine-colored, and loaded with urates and phosphates.

April 13th.—Almost a month of lull. Pain has been prevented—"nipped in the bud"—by the vigilance of the attendants, the parents and sisters of the patient. Room has been kept, as far as possible, at one uniform temperature (70° F.) By flannel clothing, frictions, stimulating and anodyne embrocations, care as to diet (which has consisted largely of milk, with porridge, Graham bread, beef pulp and beef juice, wine and egg), by the judicious use of croton chloral and valerian, the sick girl has been made as comfortable as possible. To-day there has been a violent outbreak of pain and spasm. The morphia and atropia failed. One drachm and a half of McMunn's elix. of opium was introduced subcutaneously in the neighborhood of the left shoulder, the pain being most violent there. These injections were made at intervals of fifteen minutes, three in number, and sufficed to quell the storm. The pain was of the character before described.

April 14th.—Return of pain, in both sides and shoulders (*i. e.*, leaping from one part to another). Marked spasm of pectorals, intercostals, and occasionally of diaphragm. Some opisthotonos, which I judged to be mostly voluntary, induced in order to relieve the pain in the shoulders and the scapular regions. Hiccough and difficult deglutition, from reflex disturbances of constrictor muscles and diaphragm. (It is a little singular that the nerves of the brachial plexuses seem to have escaped in all these attacks.) The pulse and breathing were accelerated, and there was considerable feverish heat (101–102 F.) Headache, with vertigo.

Have we here a case of meningeal congestion, bordering on inflammation, or may it be possible that these recent exacerbations, with fever, opisthotonos, severe clonic spasms, etc., are the result of the heroic doses that have been given of elix. of opium to relieve the pain? I confess to having yielded to the persuasion that I had here a case of meningeal congestion—my former diagnosis of neuralgia having been incorrect! Dr. Howe, who saw the young lady with me, coincided in this view. Later, however, we saw reason to change our mind. Ergot and brom. pot. was prescribed; counter-irritation by croton oil over spine (blisters were contra-indicated by the dorsal decubitus of patient), and hypodermics of McMunn or Battley, *pro re nata.*

April 17th.—Another "fearful" day. Pain and spasm in most of the voluntary muscles supplied by the lower cervical and upper dorsal nerves. Four hypodermics of McMunn, at intervals of half an hour, were injected into the left deltoid.* A stupor, lasting twelve hours, ensued.

During the attack all the members were at times convulsed, and the backward bending of the body was very marked. Difficult deglutition, weak, rapid pulse; rapid, sometimes sighing respiration. When free from pain, complete prostration; headache, stupor, pallor, sometimes alarming lividity of countenance, coldness of extremities—in fact, death at times seemed imminent.

April 18th.—Ol. tiglii over spine, from occiput to lumbar region.

April 19th.—Another severe attack of pain, which was relieved by McMunn. The croton oil is causing much suffering.

May 24th.—There has been no return of pain to date. The effect of the croton oil application has been severe, but apparently beneficial. What is its *modus operandi?* Has it acted as a persistent, powerful stimulus to the trophic spinal centres of the diseased sensory nerves? †

For about a fortnight one of the morphia suppositories of the U. S. P. was used every night. Then a 3 gr. hyoscyamus pill was substituted, with equally good results. An occasional dose of chloral or valerian. Neurotics seemed now to have their ordinary effect, as when administered to patients generally. Diet largely nitrogenous, with milk, cream, wine, etc. There was gradual subsidence of muscular soreness; the left shoulder by degrees became less irritable, and went back to its place. At the date last given, Miss R. could sit up for hours; appetite and sleep were good. To no particular medication could this good result be attributed. In fact, it is impossible to say that desperate attempts, at different times made, to bring relief to the agonizing pain, may not have done this poor girl harm. Yet it is hard to sit and fold the hands, and make no effort to relieve intense suffering. It is hard for the sympathizing physician to say, "I can do nothing." The change of weather, from the

* Pressure in these cases seems to act by abolishing the conductivity of the sensory nerves. "We are able to understand how pressure, by deranging that delicate molecular balance which makes possible the alternation of isomeric states, may prevent the passage of nervous discharges."—Herbert Spencer's Principles of Psychology, vol. 1, p. 77.

† ℞ Croton chloral ..... ʒ ij.

S. gr. ij. *pro re nata.*

* No abscess followed these injections, though considerable cellular cutaneous inflammation supervened.

† These are believed to be the ganglia of the posterior roots.—See Vulpian, op. cit.

cold of winter to the genial warmth of spring, would naturally contribute toward recovery.

June 30th.—There has as yet been no relapse. Miss R. is now able to sit up all day; has been down stairs; in fact, takes her meals with the family. Little medicine is taken; much porter and wine. Has gained in flesh. Functions regular.

July 10th.—A very severe attack, confined principally to the right side and shoulder. I was present from 8 A.M. till nearly noon. Three subcutaneous injections of Battley's sedative solution failed to give relief. What they did do was to cause fever, thirst, headache, stupor, finally delirium, lasting several hours.

July 11th.—More or less vomiting all night. Stomach still irritable. Headache and mental confusion. Pain at times very severe in the side. Hydrate chloral, with bromid. potas. was given in large, frequent doses, by enema, with starch. This eventually quelled the pain. I resolved never to give opium, in any shape, to this patient again.

July 12th, evening.—I had tried so many things by hypodermic injection, that I resolved, if another severe paroxysm should occur, to inject three syringefuls of a saturated solution of bromide potassium, expecting to see its sedative effects manifested more speedily and more thoroughly. Accordingly, on a return of the pain in left shoulder this evening, I carried out my resolution. Never was poor mortal more disappointed in an expected result. Agonizing pain followed in the point of puncture. The pain in shoulder was lost in the intenser pain in the back of right forearm, where the prick of the hypodermic needle was made. After hours of suffering, worn out, the poor girl fell asleep.

July 20th.—That arm has proved a serious trouble. Almost constant pain has been felt in the point where the bromide was injected, and a new focus of neuralgia has evidently been generated.* There has been no pain of any account elsewhere. The whole of the forearm, moreover, is swollen, and the swelling has pointed in the middle of the back of the forearm, near the site of the unlucky puncture. The indications of a formation of pus are plain enough. Poultices have been used for several days.

July 21st.—Opened the abscess in back of forearm; though there was a considerable flow of matter, the pain was not much relieved.

I was perplexed at the result of the bromide injection, and tried three syringefuls of the same on myself, one night on going to bed. There was excessive pain for a few minutes at the seat of puncture, till the drug was all absorbed; then a sleep of extraordinary soundness followed, vomiting ensuing on waking. The arm felt the next day as it usually does after the puncture of the hypodermic needle; no inflammation followed. There is no doubt that, in the case of my patient, the drachm of bromide solution injected was all absorbed in less than half an hour. Whence, then, the pain and other after bad effects? I think we can understand them only on the supposition that some injury was done by the needle to the terminal filaments of certain sensory nerves. The neuritis resulting by reflex action caused profound nutritive disturbances in the surrounding textures; there was a free migration of germinal cells to the part, and eventually an abundant pus formation. But why did this never occur before? *Nescio.*

* Jaccoud mentions (op. cit.) that severe neuralgia has followed the puncture of a lancet in venesection. Erb, in Ziemssen, alludes to facts of like nature.

July 30.—The swelling has mostly left the arm; there is now but little purulent discharge, but there are frequent paroxysms of pain, lasting for hours—sometimes all night. *This pain is mostly in the arm and about the puncture.* The arm continues disabled, and hyperæsthesia is marked over the region of pain. Morphia in ointment (3 j. to the 3 j. of cerate) has seemed to afford great relief; so also has belladonna extract, beaten up with water and applied in the form of a poultice.

She has been taking the past week the following prescription:

℞ Tinct. fer. mur. ..... 3 ij.
Bromide pot. ..... ss.
Water ..... ℥ vj.
M.
Sig.—A tablespoonful three times a day.

Aug. 30th.—The condition of Miss R. for the past month has been slowly improving; no violent attacks of pain. The arm is getting better, yet it is subject to brief attacks of pain at the place of puncture. Pain in the left shoulder has once or twice been awakened by an attempt to use the arm, or by hurting the shoulder when moving her. She is now able to sit up several hours each day, and has recovered her habits of sleep.

Sept. 5th.—I have only to add that several attacks of pain have apparently been warded off by a resort to a saturated tincture of gelseminum, in half-teaspoonful doses, till the physiological effects of the drug on the eyes and head have been experienced. Sometimes the external application of the tincture to the side has been sufficient.

I ought to add a word respecting the remarkable tolerance of narcotics and anæsthetics evinced during the neuralgic paroxysms. So far these paroxysms have their analogue in an ordinary case of tetanus. When any one can explain why, in tetanus, an irritation springing from a peripheral nerve, or nerves (as of the sensory nerves of the fingers or toes in frost-bite, lacerated wounds, etc.), can so agitate the whole spinal nervous system as to cause motor disturbances that are but little influenced by the most powerful remedial agents, one can explain why peripheral irritations of a *less high and persistent grade* (as in the case above recorded) resist large doses of opium and anæsthetics. Chloral, which so wonderfully mitigates the violence of traumatic tetanus, and which, in a severe case of hydrophobia which lately occurred in this vicinity, gave much relief when all other means failed, might be expected to do good in neuralgia characterized by the tetanoid element (hyperæsthesia, local spasm, tetany of the shoulder, etc., as illustrated in my report). Unfortunately, however, the large doses that are necessary to control the paroxysms are not tolerated by our patient's stomach (irritable at such times), and the hypodermic method of introducing the remedy into the circulation, considering my late unfortunate experience with the potassium bromide, I shall not be in any haste to try.

Oct. 21st.—Since the foregoing article was written, several opportunities have occurred for testing the remedial powers of the tincture of gelseminum in this case. So far the experiment has been satisfactory. The pain and spasm seem to be controlled by the remedy. Half-drachm doses proved to be more than was necessary—pain was relieved, but headache and disturbed vision followed. Ten, and even *five*-drop doses have proved to be enough to promptly arrest incipient attacks. No unpleasant effects have followed the smaller doses. It is not, however, positively known whether the incipient attacks, thus promptly cut short,

would have merged into the more violent paroxysms that have hitherto so often defied treatment. Certainly no opportunity has yet occurred of trying the gelseminum under *the most* unfavorable circumstances. The presumption, however, is (and I am sustained by the opinion of the father of the young lady, a man of rare judgment and discernment) that the *minor* attacks would very soon have led to the *severer*, and that the gelseminum has proved of rare utility.

With the cessation of pain, Miss R. has greatly improved in health, and the hyperæsthesia of the left shoulder is less marked than it has been for many months. She can now use the left arm a little, but the right arm and hand are still disabled; the condition of the latter is slowly improving under the use of hot salt-water baths. She sits up nearly all day, and has resumed her place in the family circle.

SYPHILIS OF THE COCHLEA (COCHLITIS?).

By D. B. ST. JOHN ROOSA, M.D.,

SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL.

Some three years and a half since, in writing upon diseases of the labyrinth, I stated that I had yet to see a case of recovery from syphilitic disease of that part of the ear.* Since that time I have reported one case of cure of syphilis of the cochlea by the use of mercury and potash.† I have also very lately seen a similar case in which very great improvement has resulted from an anti-syphilitic treatment—so great an one, that we may hope for much more, since the case has been under treatment but a month. These cases have of course made me more hopeful as to the prognosis of syphilitic disease of the labyrinth. They, with some others that I will now report, have also assisted me to a clearer idea of the symptoms and nature of the disease, although much remains that is unpleasantly obscure, especially as to the pathology. This much is certain, however: the clinical investigation of recent cases will aid us very much in determining just how to distinguish diseases of the labyrinth from those of the middle ear, and perhaps to go a step farther, and locate them in the vestibule, semicircular canals, or cochlea. I beg therefore to again report the outline of the first case alluded to, with the additional ones. Before doing so, the symptoms that may be somewhat relied upon in making a diagnosis of disease of the cochlea and of the other parts of the labyrinth will be tabulated.

1. Disease of the cochlea, as of the other parts of the labyrinth, usually, although not always, manifests itself suddenly. The patient can definitely fix upon a time when he became deaf, and when he began to have *tinnitus aurium*. This is true even when one side only is affected. The one-sided deafness would not be so quickly recognized were it not usually accompanied by tinnitus, vertigo, and often by unsteadiness of gait. Sudden loss of hearing and the sudden occurrence of tinnitus, vertigo, and staggering, are not, however, entirely peculiar to labyrinth disease, since it is well known that we sometimes, although rarely, have the same symptoms in cases of inspissated cerumen and catarrh of the middle ear. They are therefore only of pathognomonic value in connection with the objective examination and tests.

2. The tuning fork is usually heard better or only in the sound or better ear. This would be a much more valuable test were the average powers of exact and objective examination better than we find them among our patients. The value of the tuning-fork is impaired by the willingness of even intelligent patients to believe that they hear all kinds of sounds, no matter how produced, better with the better ear. Then again, if both ears be affected, to nearly the same degree, the test has an extremely limited value.

3. The examination of the membrana tympani and the employment of the methods for inflating the middle ear, will usually give us reasonable conclusions as to the situation of a given disease of the ear, so that at the least we may exclude collections of fluid in the tympanic cavity in making a differential diagnosis between disease of the middle ear and of the labyrinth.

4. The piano, or any very similar musical instrument, will aid us in determining whether or not disease of the cochlea exists. The examination of cases that were unquestionably affections of the labyrinth shows that the power of appreciating low tones is the last to suffer, and the first to recover in most cases of disease of this part of the ear, so that these will be heard when the high ones are not heard at all, or if they are appreciated, they appear "*false*" or doubled. From our present knowledge of the physiology of hearing, when these symptoms are present, we must conclude that the cochlea is the seat of disease, even if it be secondarily affected.

5. The diagnosis of *syphilis* of the labyrinth depends in a great measure upon the same kind of evidence as that from which we conclude that a case of optic neuritis or choroiditis is syphilitic; that is to say, the history and the presence of other symptoms are eruption, mucous patches, etc. It should not be forgotten, however, that the occurrence of labyrinth disease, in a person who has probably had the initial lesion of syphilis, even if no other symptoms are present, is a very suspicious circumstance which should lead to a careful weighing of the indications for and against a mercurial treatment.

I prefer to say disease of the cochlea, instead of disease of the labyrinth, when the prominent symptoms, as in the cases now reported, are great impairment of hearing, the inability to hear certain tones, and the production of false ones. These are evidences, I think, of cochlear disease, whatever else we may have. Tinnitus is a symptom common to many forms of aural affections, while vertigo and unsteadiness of gait are chiefly to be referred to undue pressure from the base of the stapes upon the semicircular canals, and not to disease of the cochlea. I think too much stress has been laid upon increased pressure upon this latter named part of the ear, to the neglect of disease having its origin in the tone-perceiving apparatus—the cochlea. "Ménière's disease" has always seemed to me an unfortunate name, since it has been indiscriminately applied. It ought not to be used unless it refers to a case such as that in which a hemorrhage into the semi-circular canals was found. Of late, cases in which the cochlear symptoms are, at least, the predominant ones, are sometimes styled cases of "Ménière's disease," when they have very little in common with cases of hemorrhage. In short, I think we should, in making a diagnosis, begin to localize the part of the ear that is chiefly affected. It is interesting to notice that we are always assisted in a diagnosis of supposed cochlear disease, if the patient have a musical education. I believe all the cases of double hearing that have been reported occurred in musicians. Certainly other patients have had the same symptoms, but they have been unable to

* Treatise on Diseases of the Ear, p. 564.
† Archives of Dermatology, vol. I., part III.

appreciate them. The power of hearing certain tones can, however, be accurately tested in all patients except young children.

Case I.—W. M., æt. 37. The patient states that five weeks ago, on one particular day, he observed that his hearing was impaired and that he had a noise in his ears. From that time to this he has grown worse. He also states that his hearing is worse at night. About six months ago he had a chancre; three months later he had alopecia; and there is now a copper-colored papular eruption upon his wrists and arms.

Hearing distance: R. $\frac{0}{40}$, L. $\frac{\text{Laid}}{40}$.

The tuning-fork is heard better in the *left* ear. The pharynx is granular and in a hypersecretive condition. The drum-heads both show small light spots. The usual treatment for catarrh of the middle ears has been employed since the attack of tinnitus and the loss of hearing, but without success.

The patient was immediately placed upon anti-syphilitic treatment, which he carried out with but moderate faithfulness, but he began at once to improve. Two months after his tinnitus was relieved, and the hearing distance was: R. $\frac{\text{Pressed}}{40}$, L. $\frac{6}{40}$. After this he went under the care of Dr. Sturgis for other symptoms of syphilis, and he informed me that he heard very well.

Case II.—Mrs. X., æt. 31. April 8, 1875. Seven weeks ago this patient, who was brought to me by her husband, a physician, began to observe an impairment of hearing, accompanied by a dull pain and by tinnitus.

Hearing distance: R. $\frac{0}{40}$, L. $\frac{1}{40}$.

The husband, and the note of a physician who had supervised the treatment of the patient, state that she had not been well since the birth of her child in August last, when an abrasion (syphilitic?) was found on the *os uteri*. This the husband says was probably produced by infection from his own finger, upon which was the initial lesion of syphilis, contracted in attending a case of labor in a syphilitic patient.

The symptoms from which Mrs. X. suffered before the loss of hearing were neuralgic pains about the eyes, hyperæmia of the optic discs, papular eruption on the chest, and alopecia. There are now traces of the eruption, and the patient has a poor appetite, pains in her legs, and some neuralgia about the eyes. The treatment was anti-syphilitic in the beginning, but has not been very thoroughly carried out of late. The pharynx is granular, and the left drum has no light spot. The usual treatment for catarrh of the middle ears has been pursued to some extent, but with no benefit, for the aural symptoms are increasing.

A thorough anti-syphilitic treatment was undertaken, and, according to a note from the husband and a verbal communication from the physician who first observed the case, the patient progressed steadily to recovery under this management. I have not seen her since she first consulted me.

Case III.—Mr. U., æt. 33. August 30, 1876. The patient states that towards the end of last June he observed dulness of hearing and tinnitus in both ears. Soon after he discovered that he was totally deaf as to the left ear, and the right ear has been growing gradually worse.

On August 1st he began to have attacks of vertigo and staggering, and has had several since. He had a venereal sore on his penis about February 15th, and says he had mucous patches in his mouth and throat about the middle of March.

Hearing distance: R. $\frac{0}{40}$, L. $\frac{0}{40}$.

He hears words when spoken distinctly *into* the right ear. The drum-heads are both dull in color and have no light spots. The air enters both tympanic cavities freely upon the employment of Politzer's method, and reddens the drum-heads, but causes no improvement in hearing.

A diagnosis of syphilitic disease of the labyrinth on both sides was made by my associate, Dr. E. T. Ely, who saw him first; and after the patient had seen Dr. E. L. Keyes in consultation, he was put upon a course of inunction with the oleate of mercury, mercurial baths, and iodide of potassium internally, in steadily increasing doses.

On September 9th, he was already better. He could hear the voice much better; the attacks of vertigo continued, but there was no more staggering.

A more complete examination showed some peculiar symptoms which throw some light upon disease of the cochlea, and which are therefore now detailed. The noises of the street *jar* the patient's head very unpleasantly. He cannot distinguish sibilants—*s* sounds like *f*, etc. The notes of the piano become discordant at 5th C. They do not sound *double*, but *false*. In the higher notes the 7th note sounds more like the octave than the octave itself.

September 12th.—There is a little more improvement in the hearing. He hears notes truly about an octave higher than on the 9th. When an upper note is struck he also hears with this the half-note above. He still complains of the unpleasant effect of the noisy streets. The drugs have been steadily continued, and with no unpleasant effects. He is allowed to leave New York and go to the sea-side.

September 19th.—Patient now hears conversation with the right ear at ten feet. The left ear seems to have no power whatever. The dose of potash has now reached seventy-five grains three times a day.

October 5th.—Hears the voice at twenty feet with ease. All but the last two notes of the piano are heard correctly. *F* still sounds like *s*. Is taking one hundred and twenty grains potash three times a day. The history rests here for the present.

It is possible that we have not paid enough attention to the protection of inflamed or hyperæmic ears. As has been shown,* boiler-makers may protect their ears from the destructive hyperæmia caused by the concussions to which their work exposes them, by plugging the meatus; and telegraph-operators may suffer from an impairment of hearing induced by exposure to the continuous clicking of a telegraph instrument. In the case just reported, the patient experienced great relief from the change of residence from near the noisy pavements of New York to the quiet of the sea-side; and I believe where noise produces such a degree of irritation as was complained of in this case, we should carefully select a residence for the patient with a view to keeping him out of noise. In ophthalmic therapeutics a great deal of care is often necessary to protect the eyes from the light; and in acute aural disease, and perhaps in some forms of chronic affections, the same care should be exercised lest the ears be exposed to loud or continuous sounds.

Case IV. is one that I saw at the Manhattan Eye and Ear Hospital, through Dr. E. T. Ely, who had charge of the patient at the Eastern Dispensary, and who diagnosticated disease of the labyrinth. Mr. L., æt. 22. September 7, 1876. Complains that two days ago he was suddenly attacked by complete deaf-

* American Journal of the Medical Sciences, vol. lxviii., p. 377.

ness in the left ear, accompanied by noises like "the blowing off of steam." These symptoms have continued, and he has also had slight vertigo and feeling of unsteadiness—most troublesome when he turns his face upwards. He had a venereal sore on penis two years ago, and subsequently sore mouth, falling of his hair, and iritis. Was treated for syphilis by reputable physicians.

Hearing distance: R. $\frac{10}{40}$, L. $\frac{0}{40}$. Tuning-fork heard only on right side. Drum-heads somewhat sunken, with dull color and dull light spot. Air enters middle ears readily through Eustachian tubes, but does not improve hearing.

September 20th.—Patient has been treated for catarrh of the middle ears, without any benefit. Anti-syphilitic treatment was advised at his first visit, but he has refused it thus far.

The diagnosis in this case has not been subjected to the crucial test of treatment. Its syphilitic character cannot therefore be so strongly emphasized. Yet when a history of general syphilis is so distinct and a labyrinth affection occurs, I think we may safely conclude that the latter is at least *modified* by the venereal poison, if not actually caused by it.

It is undoubtedly true that affections occur in syphilitic patients (from suppression of the perspiration, for example) which would have occurred all the same had they not been syphilitic; and yet the exposure or imprudence having once caused the attack of inflammation, it immediately assumes the character of a syphilitic affection by reason of the syphilitic blood, whose increased flow to the part and the exudation go to constitute the inflammation. The complete failure of the anti-catarrhal treatment, although all these patients showed some catarrhal symptoms, was another striking evidence of the real nature of the cases; for we seldom meet with cases of catarrh that do not respond to some extent to the use of the catheter, Politzer's method, etc., while, in acute or sub-acute labyrinth diseases, this treatment often aggravates the symptoms.

We do not know as yet what part of the cochlea corresponds to the low, and what part to the high notes of a musical instrument; but we do know, as has been intimated in a preceding part of this article, from what has been seen of diseases of the labyrinth—not only in such cases as those just given, but in those resulting from cerebro-spinal meningitis—that the parts tuned for low tones suffer less than the others. The former will remain unhurt, or at least with a certain power of perceiving sound, when the latter have no power at all. I have now a patient under observation, however, who seems to have labyrinth disease secondary to a catarrhal affection of the middle ears, who presents some symptoms that seem to contradict this view. With the right ear—the one in which I think the nerve is diseased—he can hear the high notes of a piano better than the low ones; in walking on the sea-shore he hears the crickets in the grass, but not the roar of the waves; he can hear the chirping of insects and the movements of their bodies easily; the tick of a watch is heard normally $\frac{4}{40}$, and yet he cannot hear the tones of the human voice at all well. With the left ear, whose hearing distance for the watch is but $\frac{1}{40}$, the power of hearing conversation is so good that the patient, a young man of seventeen, carries on his studies at college with no particular difficulty.

These clinical facts may yet be fully explained by the physicist working with musical instruments; at least, as soon as the pathologist has determined the exact nature of the diseases of the cochlea.

Progress of Medical Science.

Retropharyngeal Abscesses in Children.—The *Jahrbuch für Kinderheilkunde* contains a paper by Prof. Bókai, of Pesth, on this subject, based on 144 cases of the disease observed and treated by him in the Children's Hospital at Pesth, between the years 1854 and 1876. Of these cases 129 were idiopathic; 3 were secondary to abscesses in the neck; 4 were secondary to spondylitis cervicalis; 7 occurred during the course of scarlet fever, and ought properly to be classed with the idiopathic cases, as the anatomical processes in both were the same; and finally, 1 was of traumatic origin. In addition to these, he observed 43 cases of lymphadenitis retropharyngealis, which he classes with the idiopathic retropharyngeal abscesses, because he believes that the latter always result from the former. Formerly he believed that catarrhal pharyngitis was the cause of retropharyngeal abscess, but his observations convinced him many years ago that the abscess was always developed from a lymphadenitis retropharyngealis. The existence of several small lymphatic glands in the retropharyngeal connective tissue has been demonstrated by Hyrtl, Luschka, Henle, and other anatomists. In 30 autopsies of children made by Dr. Dollinger at the Children's Hospital in Pesth, the deep cervical glands were found, as described by Henle, to be from the size of a millet-seed to that of a pea, in 20 cases; in 7 cases, in which death had occurred from catarrhal pneumonia, they were from the size of a bean to that of a hazelnut, but unchanged in structure; in the three other cases they were cheesy. Prof. Bókai has frequently been able to observe idiopathic retropharyngeal abscesses in all the stages of their development. In these cases he always found at first a firm tumor, as large as a hazelnut or a pigeon's egg, behind one or other tonsil, rarely in the middle of the retropharyngeal space. These tumors could be felt externally by deep pressure near the angle of the jaw. Later on, they became soft and elastic, fluctuated, and gave exit to pus when opened. The secondary retropharyngeal abscesses, which are due to burrowing of pus from abscesses in the external parts of the neck, and also those which are due to disease of the vertebræ, are comparatively rare. It must be remembered, however, that a considerable number of the retropharyngeal abscesses in scrofulous children, though accompanied by suppuration of the superficial glands, are really idiopathic, and not due to burrowing of pus. The retropharyngeal abscesses that complicate scarlet fever are also due to lymphadenitis, and only differ from the idiopathic abscesses when septicæmia sets in in the course of a scarlatina diphtheritica.

The affection is met with about as often in girls as in boys. It is most frequent during the first three years of life; after the third year it rarely occurs. It occurs less frequently in summer than in the other seasons of the year, and in general it may be said that the same conditions of temperature that favor the development of ordinary inflammations of the throat, also predispose to the development of retropharyngeal lymphadenitis and abscess. Scrofula, which predisposes to inflammation of the lymphatic glands in general, is a very important predisposing cause of this affection. The influence of local affections of the mouth and throat on the neighboring lymphatic glands must not be overlooked. Indeed, the frequency

of diseases of the mouth and throat in children may account for the fact that retropharyngeal abscesses are almost exclusively met with in the early years of life. Pharyngitis does not excite the formation of an abscess by direct extension of inflammation to the retropharyngeal connective tissue, but in the same way that eczema of the head, for instance, causes swelling and inflammation of the neighboring glands.

The disease may follow a very acute or a very chronic course. The abscesses may be formed in two days, or they may require eight weeks or more for their development. The course is generally acute in nurselings. The symptoms consist in difficult deglutition; a peculiar, muffled tone of voice, but no hoarseness in uncomplicated cases; more or less marked disturbances of respiration and circulation; snoring during sleep; occasionally cough, stiffness of the neck, moderate fever, emaciation in chronic cases, regurgitation of food and vomiting, and in rare cases convulsions. Inspection of the throat will reveal a large amount of tough mucus, narrowing of the fauces, and redness of the mucous membrane, and, when a good view of the posterior wall of the pharynx can be obtained, a tumor of greater or less size, and of the same color as the mucous membrane. The tumor is rarely in the middle line. When suppuration has set in, it appears paler and yellowish. In most cases, however, inspection will fail to reveal the tumor, and digital exploration must be resorted to. This will afford the most reliable testimony, and if rapidly made will cause but little vomiting or suffocation. External palpation in the neighborhood of the angle of the jaw is also useful, both to determine the presence of the tumor and to ascertain the existence of fluctuation. The symptoms of the retropharyngeal abscesses which complicate scarlet fever or diphtheria are generally overshadowed by those of the primary affection. It is, however, a very rare complication of diphtheria. The secondary retropharyngeal abscesses generally run a very slow and chronic course.

Although this is one of the most severe and dangerous affections of childhood, only 11 of the 144 cases observed by Prof. Bókai proved fatal. Spontaneous opening of the abscess occurred in 19 of these 144 cases; but in general this is a rare occurrence, and death is apt to result when an early opening is not made. An opening will often save the child when it is apparently in the throes of death. The younger the child the worse the prognosis. The escaping pus may get into the air-passages and cause suffocation if the child be too young or too weak to expel it by coughing. In two of Prof. Bókai's cases pus got into the trachea and asphyxiated the children; but respiratory movements and cough were excited by the application of electricity, and life was restored. Pneumonia may result from the introduction of pus into the air-cells. Facial paralysis occurred in 3 of the 144 cases. All cases of lymphadenitis do not go on to suppuration, resolution setting in in many cases.

In the treatment, internal remedies are useless except when indicated by the presence of complications or of constitutional diseases. In the acute cases, frequently changed cold applications to the neck are most useful in the first stage. Ice may be given if the children can be made to suck it. Leeches do not seem to do much good. In chronic cases the cold applications may be of an irritant character and need not be changed so often. As soon as suppuration begins, poultices should be substituted for the cold applications. As soon as fluctuation is distinct, especially if the disturbances of deglutition or of respiration are marked, the abscess should be opened. This will be most easily done with the knife, but sometimes the thin wall may be bored through with the finger. Light pressure on the affected side of the neck will render the tumor more tense and facilitate both the opening and the escape of the pus. Bending the head slightly forwards will facilitate the escape of the pus through the fauces and mouth. The pharynx must subsequently be kept clean by gargling or by injections with lukewarm water, and a reaccumulation of pus prevented by keeping the wound open. The hemorrhage is generally slight, but if excessive may be controlled by cold injections. In some rare cases the abscesses may be opened externally at the side of the neck.—*Jahrbuch für Kinderheilkunde*, Band X., Heft 1 and 2.

Rare Case of Hip Dislocation.—Dr. William A. Johnston reports a case, seen in the surgical clinic of Prof. Gross, of a child seven years old, who when six months of age had a fall, followed by the deformity common to iliac dislocations. Prof. Gross called attention to the infrequency of this injury in the young, because the force necessary to induce such an injury would rather lead to separation of the epiphysis of the bone, owing to its imperfect development and consequent inability to resist external injury. He considered the case remarkable, and one he had never seen at this age, nor did he think there was a similar one on record. Reduction would be useless, as there was no acetabulum, the cavity having been absorbed and filled up.—*Philadelphia Medical Times*, Oct. 14, 1876.

Injections of Carbolic Acid for Neuralgia.—Dr. Merteu, of Neuwedell, reports four cases of severe neuralgia that were cured with surprising rapidity by one or two hypodermic injections of carbolic acid. In the first case, the patient, a hysterical young woman, had suffered for several months from strabismus and ptosis of the left eye, with diminution of the field of vision in the same eye by almost one-half. Ophthalmoscopic examination gave negative results. She was suddenly seized with intense neuralgia of the left malar nerve, for which 20 drops of a 2 per cent. solution of carbolic acid was injected over the cheek-bone. It caused at first intense burning pain, with redness and swelling at the point of injection, but one hour later all pain had entirely disappeared. On the next morning there was no pain at all, the ptosis and strabismus had entirely disappeared, and the field of vision of the left eye had markedly increased. Unfortunately, the patient did not again present herself for observation.

The second case was one of acute oöphoritis, with severe neuralgia of the external cutaneous nerve of the thigh, and intense pain about the anus on defecation. Two injections of a syringeful of the 2 per cent. acid solution permanently relieved all the pains.

The third case was one of suppressio mensium and sciatica. Two hours after the injection of a syringeful of the above solution the pain ceased entirely and did not return. Menstruation was subsequently regular.

The last case was one of myalgia of the right side of the neck consequent on exposure to cold. A single injection of the 2 per cent. solution produced a cure.—*Allgem. Med. Cent. Zeit.*, Sept. 6, 1876.

Abolition of Mechanical Restraints for the Insane.—Dr. J. L. Bodine, of Trenton, N. J., read a very able paper on this subject at the recent meeting of the Social Science Association, at Saratoga.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, November 18, 1876.

THE HEALTH OF PHILADELPHIA.

In a recent issue we drew the attention of our readers to some facts which were collected in Philadelphia, bearing on the health of that city, and we then showed by comparative statements that there had been a decided increase in typhoid, which is now believed to be largely influenced, if not actually produced, by imperfect sewerage or polluted water. The question is one which is not interesting to New Yorkers alone, but to the whole country, and we felt gratified in being able to make certain tolerably definite statements in regard to the actual facts in the case.

To many persons it may have appeared that in so doing we failed to show all the facts, for it is well known that a great deal of sickness, especially of a diarrhœal nature, has attacked persons after they visited the Centennial Exhibition. Rumors have also been prevalent to the effect that many have died of typhoid after their return. Almost every physician in the country has cognizance of one or more such cases.

Probably the reports about them have been much exaggerated, but at the same time there is doubtless some truth in the matter.

In the article referred to we showed that both the sewerage is bad and the water is more or less polluted, and that at one time it contained a pretty large amount of sewage. We are not prepared to say now, any more than then, that these unhygienic conditions were related to typhoid as cause and effect, because it may still appear that the increase has been as great in other localities—in fact, that we have been suffering from a general epidemic of the disease all over the country.

The benefit of this possibility we are willing to give to our Philadelphia friends; but we are rather surprised to find it stated by our contemporary, the *Philadelphia Medical Times*, that the Quaker city, "this summer, has been extraordinarily healthy, and that the water supply and the general hygienic arrangements have stood the very severe test so well as to reflect credit upon the city authorities and to demonstrate the great value of the homestead method of living practised in this city."

In the face of the large comparative mortality this summer from typhoid, we fail to see where either the "homestead method" or the "civil authorities" are deserving of any special credit. But this is a matter of little consequence. We are more surprised, however, to find it further announced "how much better the Philadelphia doctors are than those of New York." We might pardon this innocent conceit, which seems to be also a disease of an epidemic character in Philadelphia, but, as we have already stated, the facts are the other way, for typhoid fever, about which alone there is discussion, has shown a far greater comparative mortality in Philadelphia, this season, than in New York. We do not, of course, infer that it was owing to the doctors, for may it not have been the water or the sewage? We have no doubt, however, that the matter has been really exaggerated by the secular papers; but our friends, in their attempt to disprove such sensational statements, display a ridiculous sensitiveness in regard to a supposed conspiracy against the success of the Exhibition. We are told that "extraordinary efforts have been made by certain newspapers to injure the Centennial Exhibition," etc.

Perhaps this is an excusable anxiety, inasmuch as any allusion to the manner in which the Centennial wheel has revolved is a reflection upon the watchfulness of the flies upon it.

Reviews and Notices of Books.

THE STUDENT'S GUIDE TO DENTAL ANATOMY AND SURGERY. By HENRY SEWILL, Member of the Royal College of Surgeons and Licentiate in Dental Surgery, Dentist to the West London Hospital, etc., etc. Philadelphia: Lindsay & Blakiston. 1876.

This book is elementary. It has been the aim of the author to handle his subject concisely and independently of needless technicalities, and in that respect he has been quite successful. The first chapter is devoted to the anatomy and histology of the teeth. In the second the author takes up the subject of development of the teeth and sets forth doctrines which are somewhat at variance with those advanced by Goodsir, which have heretofore been quite generally received. It is here stated that, as early as the seventh week of intrauterine life, the first trace of dental development becomes visible, and from that period the successive steps are clearly traced and illustrated.

The third and fourth chapters are devoted to the study of the growth of the jaws, dentition, malformations and irregularities of the teeth.

In the two chapters immediately following the subject of dental caries and its treatment are considered. The author believes the great cause of caries to be an acid, and that the acid is derived from the oral mucous membrane, from decomposing particles of food, or from any food containing fermenting albuminoid substances.

When the decay has been once established, it is hastened by the development of low vegetable organisms. It is believed, however, that the leptothrix buccalis plays only a second part in dental caries, and only has some share in hastening the destruction of the already decomposing parts.

The subject of treatment is divided into preventive, which embraces thorough cleanliness, the use of strong alkaline, bland and soluble substances for washes, and powders; into treatment of the incipient stage; and then follows a lengthy description of the operation of filling teeth.

In the seventh and eighth chapters are studied exposure of the pulp, diseases of the pulp, dental periostitis, alveolar abscess, periostitis and necrosis of the maxillæ, dental exostosis and necrosis, and absorption of roots of permanent teeth. A chapter on disease of the gums and oral mucous membrane follows in order, and is immediately succeeded by a chapter on abrasion of the teeth and mechanical injuries. The remaining portion of the book contains chapters upon salivary calculus or tartar; morbid growth connected with the teeth, and such as odontomes, cysts of the jaw, epulis, etc.; diseases of the antrum; pivoting teeth; neuralgia and diseases of the nervous system; and, lastly, extraction of teeth.

The book is well written, is fairly illustrated, and is a convenient handbook for the student.

Transactions of the New York Odontological Society. Regular Meeting, Extra Session, December 20th and 21st, 1875. Philadelphia: Samuel S. White. 1876.

This volume of 117 pages contains much that is interesting, not only to dentists, but to the general practitioner of medicine. It is prefaced by the names of the officers of the Society, and has for its contents the papers read and the discussions to which they gave rise.

The first paper consists of "Notes from the Practice" of Dr. W. G. Burs, of Montreal. The second is upon "Food; its Relation to the Teeth," and its author, Dr. L. D. Shephard, of Boston, notes some interesting results obtained by proper diet, especially oatmeal and whole wheat, which contain elements essentially necessary for the support of the osseous, nervous, and muscular tissue. Dr. N. W. Hawes, of Boston, read the third paper, and in it considered the proper management of the "Sixth-year Molars." He disapproves of the removal of these teeth, because of pressure, and on the ground that their places will be filled by the twelve-year molars, for the reason that if continued future generations will have a contracted jaw by inheritance.

The fourth paper is upon "Facial Neuralgia," and was read by Dr. C. N. Pierce, of Philadelphia. Dr. Pierce justly mentions the importance of acquiring a thorough knowledge of general histology, physiology, pathology, and therapeutics, if the dentist would most successfully avoid embarrassment and mortification in his practice.

The next paper is from the pen of C. Spence Bate, F.R.S., of Plymouth, England, and is entitled "The Antiseptic Treatment of the Dental Pulp and Pulp Cavity."

Dr. Wm. H. Atkinson, of New York, next read a paper on "Necrosis and Caries, Formation of Pus, and Inflammation defined: in which the doctrine is advanced that the pus is dead blood, and that inflammation is a disturbance of the tensional harmony in the current of nutrition."

"The Chemistry of Dental Caries" is presented in a paper by Dr. S. B. Palmer, of Syracuse, in which occasion is taken to study the first principles and laws accounting for so much that is mysterious in us. The author of this paper struggles at some length among "electro-capillary currents," "local circuits," "principles of solution," "single and double fluid principles and species," "acid manufactory," etc., and comes to the conclusion that, "if we wish to consult nature's laws, we must not look in the attic of theories and speculation, but in the foundation of fact and truth where they were put in the morning of creation." The conclusion is good, but the trouble is, how are we to be assured that the "foundation of fact and truth" has been reached?

"Pressure and Contact as Causes of Dental Decay" is the title of a paper read by Dr. Henry S. Chase, of St. Louis, and was followed by a paper on "Practical Lessons in Comparative Odontology," from the pen of Charles S. Jones, M.A., M.R., C.S., London, England.

"The Influence of Vital Force in Restoring Dental Caries" is considered by M. S. Dean, of Chicago, and the author advocates the existence of a "special vital force," although it may not be able to manifest itself independently of the chemical and physical forces.

The last paper is upon "The Practical Results Obtained with Plastic Fillings, as compared with Theoretical Tests," by Thomas Fletcher, M.C.S., Warrington, England.

The papers by Drs. Beers, Shephard, Pierce and Jones are illustrated with wood-cuts.

The discussions to which the papers gave rise are lively and interesting. We have carefully looked, but have not been able to determine, *where* the regular meeting, extra session, of the New York Odontological Society for the year 1875, was held.

Compendium of Histology: Twenty-four Lectures. By Heinrich Frey, Professor. Translated from the German, by permission of the author, by George R. Cutter, M.D. Illustrated by 208 engravings on wood. New York: G. P. Putnam's Sons. 1876.

This compend contains the most essential facts in Histology desirable for students and practising physicians. It meets an oft-expressed desire, and the learned author has succeeded most admirably in his work.

The text is arranged in the form of lectures, of which there are twenty-four. The hand-books of Histology have been made so voluminous that a concise and yet comprehensive statement of the important facts relating to this branch of our science cannot fail to be greeted with pleasurable considerations. The well-established reputation of the author as a histologist is a sufficient guarantee for the excellence of the book.

The first lecture is general, and is devoted to the study of protoplasm, the cell, and its derivatives. In the second, a classification of tissues is given. In the third, the cell-layer, which covers the external as well as the internal surface of the body, is studied under the head of The Epidermis, or the Epithelium. The connective-substance group, embracing cartilage, gelatinous tissue, reticular connective tissue, and fat, is taken up in the fourth lecture; and the study of true connective tissue follows in the fifth. In the sixth and seventh lectures the histology of bone tissue, dentine, enamel, and lens tissue, is given; while the eighth is consumed entirely by muscular tissue. The blood-vessels form the subject of the ninth; and their intimate relation to the lymphatic glands and the lymphatics is shown in the tenth lecture. This, naturally enough, leads to observations upon lymphoid organs, or the so-called blood-vascular organs, in older times

erroneously called "glands," which make up the eleventh lecture. The histology of gland tissue appears in the twelfth lecture; and the relatively simple nature of the digestive apparatus, with its glands, is taught in the thirteenth; while the pancreas and the liver, with its peculiarities, are considered in the fourteenth. The lungs absorb the fifteenth lecture; and the kidneys, with the urinary passages, eliminate the sixteenth; while conceptions, with reference to the histology of the female generative glands, are introduced in the seventeenth; and these are followed by a presentation of that of the male generative glands in the eighteenth. The nineteenth and twentieth lectures are devoted to nerve tissue, and the arrangement and termination of nerve fibres. The histology of the central organs of the nervous system follows in lectures twenty-one and twenty-two; and from these the author passes to the organs of sense. The last lecture gives us the histology of the eye.

The translation is very good, fully sustaining the translator's reputation. The book is bound in good style, is printed on excellent paper, and in large, clear type, and does its publishers very great credit. It is far superior in appearance to the American edition of the author's larger work upon Histology.

ETUDES HISTOLOGIQUES SUR LE LABYRINTHE MEMBRANEUX, ET PLUS SPÉCIALEMENT SUR LE LIMAÇON CHEZ LES REPTILES ET LES OISEAUX. Par PAUL MEYER. Strasbourg, 1876.

THIS work, as its title states, is a histological study of the membranous labyrinth (of the ear), and more particularly of the cochlea, of certain reptiles and birds. It covers 180 pages, and is illustrated by five colored lithographic plates, very beautifully executed. The territory explored by the author is one with which anatomists are already familiar, through the labors of Breschet, Deiters, Reissner, Hasse, Hensen, Claudius, Boetteher, Max Schultze, Waldeyer, and others. In fact, so thoroughly have these observers done their work, that but few points in the minute anatomy of the labyrinth still remain to be cleared up. Under these circumstances it seems almost a matter for regret that so much time should have been spent by the author in travelling the beaten road, when light is urgently wanted on points like the following: the exact anatomical relations of the membrana tectoria (Corti's membrane), whether attached at both edges or only at one; the terminal distribution of the nerve fibrils, whether supplied to the inner and outer hearing cells exclusively or also to other structures in Corti's organ; the existence or non-existence of the "helicotrema," and, if present, what is its size, shape, and relations. The patient and careful investigations of which this volume gives evidence would have surely led to more valuable results had they been confined to the elucidation of any *one* of the doubtful points just enumerated, instead of being spread out over the *entire minute anatomy* of the labyrinth.

MÉMOIRES SUR LA GALVANO-CAUSTIQUE THERMIQUE. Par le DR. A. AMUSSAT FILS. Paris: Germer Baillière. 1876.

THIS volume of 125 octavo pages contains a brief historical notice of the principal applications of the galvano-cautery, and a recital of various cases treated by the author and others; together with woodcuts of morbid growths, etc., removed, and of instruments designed for the purpose of meeting certain special indications. The work will prove useful and suggestive to the surgical practitioner. The typography, paper, and cuts are better than usually found in French medical works.

A CONTRIBUTION TO THE TREATMENT OF UTERINE VERSIONS AND FLEXIONS. By EPHRAIM CUTTER, A.M., M.D. Second edition, entirely rewritten. Boston: James Campbell. 1876.

THE chief value of this work lies in those portions of it which deal with the mechanical treatment of displacements and distortions of the uterus. In the appliances which the author recommends, the base of support is chiefly extra-vaginal; this arrangement being adopted in order not to interfere with the normal tonicity of the vagina, which Dr. Cutter considers to be of prime importance in maintaining the uterus in its normal position. While we may admit that many of the intra-vaginal pessaries in common use produce an objectionable amount of lateral distention of the vagina, and that Dr. Cutter's pessaries have proved of value in practice, we cannot allow that he satisfactorily proves that dilatation of the vagina "constitutes the essential factor of the unnatural condition," or that his instruments do not "take any bearing upon the lateral vaginal walls."

In so far as they are confined to what we may term uterine orthopædics, Dr. Cutter's observations are interesting and valuable, but, when he wanders from this aspect of his theme, we find, for the most part, little else than the dogmatic statement of conclusions drawn from insufficient premises, and not always pertinent to the subject under consideration. Indeed, a large portion of the book might better have been left out, such as the lengthy diet list, the diatribe against white flour, the plea in behalf of investigators as entitled to the assistance of men of wealth, etc., etc.

The author's style of writing is deserving of the severest criticism, from which his deprecatory preface should not protect him. He seems not to know that, in writing, simplicity is the chief element of beauty, but falls into the error of so many writers who parade their solecisms as *pièces de résistance*. His errors in the use of technical terms are very numerous, some of them even betraying ignorance of anatomy, as, for instance, the expression "anterior superior spinous processes of the *ischia*," which occurs repeatedly. We are not at all surprised to find him among those who speak of "the pubis," but we must record our admiration of the perverse ingenuity which led him to supplement this common error with the expression "os pubes."

Many of the woodcuts, with which the work abounds, are admirably fitted to give currency to anatomical errors. With scarcely a single exception, those of them which show a section of the pelvis represent an inordinate distance between the pubes and the sacrum, and the vagina as attached to the uterus very near its fundus.

The book is very handsomely printed, and in every way creditable to the publishers.

A RELIABLE SIGN OF DEATH.—This sign consists in the absence of contraction of the pupil, after puncture of the cornea and evacuation of the aqueous humor. When the pupil contracts, life is still present; when it remains immovable, it is a certain sign of death. The puncture of the cornea may be made with a cataract knife, or even an ordinary lancet. It is a harmless operation.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 11, 1876.

Dr. Chas. K. Briddon, President, in the Chair.

MORBUS COXARIUS—THE ADVISABILITY OF AN EARLY OPERATION.

Dr. Sayre presented two specimens of exsection of the hip for morbus coxarius, with the following remarks:

Case No. 64.—James A. McLaren, aged four, 317 West Twentieth street, three years ago fell from a crib, and was never able to stand upon his right leg afterwards. No treatment was applied for six months, when a short hip splint was applied, which made him comfortable. This was worn for seven months, when the parents removed it, thinking the child cured. Was not seen again until July, 1876, when a large abscess was opened upon the outer side of thigh.

October 11, 1876.—Since last date two other abscesses have formed on inner and anterior part of thigh. All the sinuses are discharging profusely, and the child is running down. Exseeted to-day at Bellevue Hospital. The involucrum surrounding the upper portion of shaft was very thick, causing great difficulty in removing the head. Finding it impossible to luxate the femur, it was sawed just above trochanter minor. The upper fragment was removed with great difficulty with strong forceps, when it was found that the head was entirely absorbed, and the neck had pierced the acetabulum, causing the difficulty of removal.

Case 63.—Thos. Shead, aged five, Philadelphia. Had a fall eighteen months before, and the disease followed immediately.

Was taken in two weeks after to the Orthopedic Hospital. Six months after an abscess formed and was opened, and continued to discharge until the present time.

September 7, 1876.—He was brought to the Philadelphia Hospital while I was making my report on hip disease to the International Medical Congress. In consultation with Dr. Lister, of Edinburgh, Dr. Adams, of London, Hingston, of Canada, Post, of New York, Moore, of Rochester, and others, exsection was decided upon, and I operated at the time.

The head and neck were absorbed, and acetabulum perforated. Bone was sawed off below trochanter minor, and child dressed in wire cuirass. The after treatment was left under care of Drs. Mowray and Holland. The wound healed entirely in four weeks, and in six weeks he was brought to Bellevue Hospital, New York, in the cuirass, from which he was removed, and a long splint applied, on which he could stand and walk with scarcely perceptible shortening and good motion. He returned to Philadelphia the same way.

Dr. Sayre remarked in reference to the second case, that it afforded the best possible argument for an early operation. Had such been done, there would have been no necessity for nature to throw out involucrum.

In this connection he mentioned the case of the boy who had been operated upon before suppuration had taken place, the head of the femur being simply eroded. That case healed up in six weeks, at the end of which time the child was in perfect health.

Dr. Briddon alluded to the case presented by Dr. Crosby, in which the dead bone had been imprisoned by nature. He could not understand why there should be any doubt regarding the propriety of an early operation in these cases.

Dr. Sayre.—There is such a doubt among the surgeons of Philadelphia. The operation is advised by some only as a last resort.

Dr. Briddon.—In consultation upon a case a year ago, I heard the opinion expressed by a distinguished surgeon, that the large majority of cases of morbus coxarius get well without an operation. I believe a large number of cases will recover in the better classes of society; but such recoveries take place only after long suffering, and after the limbs have become atrophied and distorted.

Dr. Sayre.—If there be progressive caries in spite of the correct hygienic treatment in the earlier stages, then the obvious duty of the surgeon is to operate without delay.

Dr. Briddon did not think it safe to say that whenever the head of the bone was supposed to be free from erosion, that an operation should not be performed, inasmuch as the acetabulum might be eroded, a condition which never could be diagnosticated until the parts were exposed.

Dr. Peters related a case which had recently come under his observation, in which an apparatus had been worn for several years, and in which there had been much suffering during that time. He was convinced that all of this could have been prevented by an early operation.

THE TREATMENT FOR TAPE-WORM.

Dr. Beverley Robinson presented a specimen of tænia, with the following history:

The patient was a female cook, aged thirty-five years, who had suffered for eighteen months with symptoms of tape-worm, but it was not until last summer that the diagnosis of the disease was made. Dr. Robinson saw her at this time, and learned that shortly before she had passed a portion of the worm. A drachm of the fluid extract of malefern was prescribed in sweetened milk, after the effects of a full dose of castor-oil. Two days after seven feet of the tænia came away. This was attended with a marked relief of all the symptoms. Notwithstanding the dose was twice repeated since then, no more of the worm was discharged.

The questions which naturally presented themselves were: 1. What caused or gave rise to the tænia? 2. Will it recur?

In reply to the first, I can merely draw attention to the fact that the patient was a *female* and a *cook*, and these circumstances, according to Warruch* and Davaine,† are very important in considering the etiology of this worm. In 206 cases of tænia solium collated by the former, there were 71 men and 135 women; and the latter believes cooks to be especially exposed to infection by tænia, owing no doubt to their frequent immediate contact with uncooked meat.

In answer to our second question, I may remark that authorities on this subject are less inclined to the belief that the expulsion of the *head* of the tænia is absolutely necessary to a successful treatment, than they formerly were. Still, as in the specimen before you, there are evidently no segments from near the head, and as this is the portion of the worm *most important because it grows most actively*,—I would not like to be too affirmative in pronouncing a perfect cure.

* Oest. Med. Jahrb., 1841, cited by Valleix.
† Traité des Entozoaires, Paris, 1860.

Dr. Robinson stated in conclusion that it was always necessary to have the worm discharged entire to secure a good recovery. He believed it possible that the head might be expelled after the natural death of the worm, independent of medicine. In fact, he believed that in most cases the medicine got more credit than it deserved, and that the discharge of the worm after the administration of a vermifuge was oftentimes a mere accident.

Dr. Sayre was most inclined to explain the effect of some vermifuges in the light of a mere coincidence.

Dr. Peters remarked that he was in the habit of treating tænia with malefern in the form of a drachm of the powder with ten drops of the oil. Three doses of this were given in the course of twenty-four hours, followed by a purgative.

Dr. Briddon had been most successful with the ethereal extract of malefern. His plan was as follows: The first day a full dose of black draught, the next day beef-tea, the next night a dose of castor-oil, and the following morning a ʒ i. to ʒ ij. of ethereal extract of malefern. Generally in three or four hours the worm came away. If the head of the tænia was not discovered in the passages, the presumption was that it had been lost; at all events, he was not inclined to repeat the medication until three months have elapsed.

ANEURISM OF AORTA BURSTING INTO TRACHEA.

Dr. R. Osgood Mason presented a specimen of aneurism of the arch of the aorta, with the following history:

Mrs. Y., æt. fifty years, was thirty years married, had never been pregnant, and had enjoyed good health during most of her life. I first saw her August 31, 1876. Her chief complaint was of pain extending from the lower part of the sternum upward and backward to the left scapula and top of the shoulder, and also down the left arm. She had some dyspnœa, especially on taking exercise, and lately a peculiar and somewhat troublesome cough. Her voice, naturally soft and musical, had become uncertain and stridulous. She had difficulty in swallowing solid food, and usually experienced considerable pain immediately after eating.

Most of these symptoms had been growing gradually worse for several months.

Physical examination showed dulness over nearly the whole left side of the chest, and increased resonance upon the right, the contrast being very marked. The vesicular character of the breathing was diminished, but not destroyed, upon the left side, and correspondingly increased upon the right. The heart was somewhat enlarged, and its action enfeebled, and there was a loud regurgitant murmur at the aortic opening. My diagnosis was a tumor, probably aneurismal in character, pressing upon the trachea and probably also upon the œsophagus—insufficiency of the aortic valves and dilatation of the left side of the heart. The main points were communicated to the patient and a consultation advised. One was accordingly arranged with Dr. Loomis for Monday, Oct. 2d. On Saturday, Sept. 30th, however, after an unusually hearty dinner, she was suddenly seized with hemorrhage, the blood bursting with violence from the nose and mouth. She fell forward upon the floor and almost immediately expired.

Post-mortem by Dr. F. R. S. Drake, twenty hours after death. Rigor mortis well marked, body well nourished, adipose tissue abundant. On opening into the cavity of the chest, considerable fluid was found in the left pleura, but no adhesions or other signs of inflammation. The lung was compressed or shrunken to about one-half its normal size.

The right pleura was slightly adherent; the lung itself was increased in size from congestion and compensatory emphysema.

Examining the heart, we found fluid to the amount of three ounces in the pericardium. There were clots in the heart and in all the large vessels connecting with it. The cavities of the left side were somewhat enlarged and the walls thinned. The ascending aorta was also considerably dilated, and the whole thoracic portion of the vessel was the subject of atheromatous degeneration. The semilunar valves were insufficient, the edges being thickened and dotted with atheromatous deposit.

Laying open the aorta along the whole arch, near the middle of the transverse portion, under the space where the subclavians and left carotid are given off, and directly in front of the trachea, there was found a large opening through the posterior wall leading into an aneurismal sac. The sac was found adherent to the anterior wall of the trachea, and at the point of adherence—just at the point where the left bronchus is given off—was found the opening into the trachea through which the fatal hemorrhage had occurred.

No other organs were examined.

In conclusion, Dr. Mason mentioned as a curious coincidence, that the husband of this lady suddenly died on the following Monday. No autopsy was made in his case.

Dr. Finnell remarked that Dr. Mason's case was one of a type which were repeatedly presented to the Society, and in which no positive symptoms of aneurism were present during life.

Dr. Sayre remarked that the change of voice was a very suspicious circumstance in connection with Dr. Mason's case.

Dr. Robinson remarked upon the value of the laryngoscope in clearing up the diagnosis of all cases in which dysphonia or aphonia was present. The diagnosis from ordinary laryngitis from simple paralysis of the vocal cords was not difficult. In the former case there was always thickening of the membrane of the cord, while in the latter they presented their usual shining appearance. Even when no dysphonia existed, it was possible to discern unmistakable modification in the movements of the cord, which were always significant, if not pathognomonic. He was in fact so strongly impressed with the value of the laryngoscope in these obscure cases, that he thought every physician should not consider his examination of a case complete without its use.

Dr. Peters remarked that in the ninety cases of aneurism of the aorta presented to the Society, the diagnosis was made in the large majority before the post-mortem examination.

Dr. Briddon referred to a case of aneurism of the arch of the aorta, in which no diagnosis of was made until a blowing sound appeared over the vertebral prominence.

Dr. Mason remarked that the point of interest to him was in regard to any known method of diagnosticating an intra-thoracic tumor from an aneurism.

Dr. Post stated that although there were no differences in symptoms between these two kinds of tumor, aneurisms were so common that there was little liability to error.

EPITHELIOMA OF THE FACE.

Dr. Post presented specimens of epithelioma of the right side of the face. The disease first showed itself two years ago, and gradually extended forward

over the ramus of the jaw, down as low as the angle of the jaw, and backward towards the mastoid region, involving the lobe of the ear and a portion of the meatus auditorius. There were no secondary enlargements discoverable. In the operation of extirpation of the mass, the lobe of the ear was sacrificed, and a portion of the wall of the meatus. After dissecting around the tumor and separating it from the subjacent parts, portions of the masseter muscles were removed. Cutting behind the ramus, a large vessel was encountered, which proved to be the external carotid artery. Dr. Hinton, who assisted at the operation, placed his finger upon the vessel until a ligature was applied. A formal dissection was then made, and no important blood-vessels having been cut, not much blood was lost. The tumor adhered to the parotid, but was not originally connected with it. Although a portion of the facial nerve was removed, the eye remained closed, at least up to the time that Dr. Post left her, which was in the progress of recovery from the effects of the ether. By economizing the integument around the lobe of the ear and sliding the skin from the neck, a very decent covering was made for the cavity left after the operation.

Dr. Finnell presented a specimen of rupture of the uterus, after which the Society adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 2, 1876.

Dr. S. S. Purple, President, in the Chair.

HOW THIRTY-FIVE CONSECUTIVE AMPUTATIONS WERE SUCCESSFULLY TREATED ONE HUNDRED YEARS AGO.

Dr. Stephen Smith read a brief but interesting paper, which consisted of a *résumé* of the method of amputation practised by Edward Alanson, in the Liverpool Infirmary, and reported in the year 1779. Alanson's report, at the time it was made, was regarded by the surgical world as incredible, and questions were raised on all sides touching its reliability.

To the statement that only carefully selected cases had been operated upon, the answer came that no refusal had been made to operate whenever the support of a single colleague could be obtained. The symptomatic fever, startings and spasms were all very slight; the pain upon dressing was only trifling; there was but little discharge, too slight to give the least trouble; there was no necessity for removing the dressings in a single instance on account of hemorrhage; there was not the smallest exfoliation of bone, except in one case; at the end of a month after the operation, the wound was healed, either perfectly, or so that less than a sixpenny piece in size remained open; the cicatrix was not tender; the stumps were not conical, and the patients could walk upon them freely. Alanson was fully alive to the dangers of foul air of hospitals, as shown by the fact that one patient was removed from the infirmary during a severe attack of erysipelas, and, after being bathed and supplied with new clothing, was placed in a new building near at hand.

The statements made by Alanson regarding his success were discredited by the average surgeon of that time, and the incredulity was due to the direct influence of results previously obtained in amputation. For amputations had been regarded as the most formidable operation in surgery, and unfavorable results had been conceded to be a necessity. The attempt which Alanson made was to secure primary union after an ample flap had been applied directly to the face of the stump. The first intimation that such a result could be obtained, was made in 1679, just a century previous, by Young, of Plymouth, in writing to Hobbs of London.

In Alanson's time it was supposed by the surgical world in general, that exfoliation of the bone was a necessity after amputation. Alanson's method of operating was briefly as follows: Taking the thigh as an example, the tourniquet was applied, the skin and muscles were drawn up by an assistant, the operator made a circular incision as quick as possible through the skin and cellular tissue, and then at the highest point to which the integument had retracted thrust the point of the knife down to the bone, and holding the instrument at a proper angle, it was carried around the limb so as to lay the bone bare about two or three fingers' breadth higher up than the edge of the cutaneous incision. In that way the muscles were dug out, as it were, and a cone-shaped cavity formed. A retractor was used, and the bone was divided with a saw as high as possible. Each and every artery was drawn out, all its attachments separated, and then secured with a slender ligature. The surface of the stump was well sponged with warm water. The skin and muscles were gently brought forward to cover the end of the bone and were supported by a flannel roller passing about the body and then down the limb smoothly and with moderate firmness until the extremity of the stump was reached. The skin and muscles were placed over the bone, so that only a bare line extended across the end of the stump, and the ligatures were left hanging out at the extremities of the incision in either side. If the skin did not easily cover the bone, strips of adhesive plaster were applied from below upwards. The many-tailed bandage was employed. The stump was placed on a pillow and raised only about half a hand's breadth; this was a special feature. The dressings were changed no oftener than was necessary to secure perfect cleanliness. In a word, the surgeon with great care and nicety aimed at primary union; and his success was all that could be desired. Though a century has passed, and during that time great advancement has been made in surgery, yet no records of successful amputation have been published which have equalled those published by Alanson in 1779.

The Reader did not think that a return to the method of treatment by leaving the stump open would ever yield such results as these.

Dr. Hunbard inquired whether the operation performed by Alanson was not the same as the old circular operation performed in the New York Hospital twenty-five years ago.

Dr. Smith replied that it was plain the operation performed by Alanson was not the one commonly adopted in making the cone at that time. In the usual method of performing the circular operation, three incisions were made. The first was through the skin; retraction was then made, and followed by an incision through a portion of the muscles, and then retraction followed by an incision down to the bone.

Alanson's method, however, was to insert the point of the knife at the highest point to which the skin had retracted, and, carrying it down through the muscles at an angle which would bring it in contact with the bone at some distance above the edge of the integument, sweep it around the limb, dividing the tissues as much as possible at one stroke. In that manner a cone was dug out, as it were, and ample material given to cover the bone, and then the effort was made to secure primary union.

No discussion ensuing, Drs. Beverley Robinson and Octavius A. White were elected Fellows, and the Academy adjourned.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, November 3, 1876.

DR. E. G. LORING, PRESIDENT, IN THE CHAIR.

THE DIFFERENTIAL INDICATIONS FOR THE USE OF THE FARADIC AND GALVANIC CURRENTS.

DR. A. D. ROCKWELL read a concise paper upon the above subject, in which the intimation was made that the relative value of the two currents in the treatment of disease was mainly a question of experience; sometimes one could be employed with the greatest benefit, sometimes the other; and sometimes the two could accomplish what neither could do alone.

It was to be believed that the experience of physicians would confirm this view. With regard to the use of electricity for the relief of pain, it had been generally supposed that galvanism was most useful; whereas the truth was, that faradism was invaluable as an agent for that purpose, and relieved in many cases in which galvanism was worse than useless. The author of the paper referred to the fact that a physical and physiological knowledge of the two currents was necessary if the medical man would use them in the most successful manner, but it was not his purpose at that time to study those, and he turned his attention to the third essential, namely, experience in their use. In general, it might be stated that the faradic current, probably by virtue of its greater mechanical effects, was tonic in its action, and that the galvanic, on account of its greater power of overcoming resistance, should be used when it was desirable to act upon the central nervous system. The latter, because of the superiority in exciting nerve irritability, was also used in the treatment of paralyzed muscles which did not respond to the faradic current.

A hasty glance was made: (1) at those conditions which demanded the faradic current; (2) at those requiring the galvanic; and (3) at those diseases, conditions, or symptoms which indicated an interchangeable use of both currents.

With regard to the first class but little was to be said, inasmuch as asthenopia was about the only distinct disease which demanded the faradic current alone. Concerning the exclusive use of galvanism, not very much more was to be said, although that current was the one more commonly employed in the treatment of spinal irritation, certain sequelæ of cerebro-spinal meningitis, and most skin diseases in which electricity had been found to be of service.

Under the third head, it had been found that paralysis was the condition in which electricity was most serviceable. In hemiplegia, when there existed an exalted electro-muscular contractility, electricity, if employed, should be in the form of faradization, with an exceedingly mild and rapidly interrupted current. In paraplegia, as a rule, galvanism alone was most serviceable. In the treatment of facial paralysis, especially when caused by cold striking against the side of the face, a much weaker current of galvanism might cause the muscles to act than was necessary in health, and the faradic might not produce any contractions whatever. After a time, however, the muscles might respond to faradism. In true neuralgia it was said that galvanism was most beneficial; while false neuralgia would yield most certainly to faradism. In the great majority of cases in which firm pressure aggravated pain, the galvanic current was indicated; but when such firm pressure over the course of the nerve did not increase the pain, the faradic current was indicated. That was a general rule, although there are some exceptions.

For the relief of the pain of herpes zoster, the galvanic current was invaluable. The tormenting, distressing, and acute pain of mammary cancer could be relieved in a remarkable manner by the use of galvanism; and although relief, as a matter of course, was not permanent, the necessity for the use of opium could be postponed for a long time, if not entirely avoided. Faradism, in the doctor's experience, had not been beneficial under like circumstances.

For the relief of chorea, amenorrhœa, associated with anæmia and debility, nervous exhaustion, in general the faradic current was advised.

In conclusion, Dr. Rockwell alluded to the tonic effect of general faradization. He was of the opinion that it had a wider range of application than any other method by which electricity could be employed, and that a thorough study of the practical use of the principles involved in that method would amply reward the practitioner for the time and labor spent in the investigation. The power of electricity as a tonic was first advanced by Dr. Rockwell, in a series of articles published in the RECORD nearly ten years ago, and it was believed that the correctness of his theory had since then been established by clinical experience.

In reply to a question, Dr. Rockwell expressed the opinion that all the beneficial effects of electricity could be better obtained through other means than electrical baths.

SOCIETY OF NEUROLOGY AND ELECTROLOGY.

Stated Meeting, October 30, 1876.

DR. J. C. DALTON, PRESIDENT, IN THE CHAIR.

EXPERIMENTS WITH MUSCARINE.

DR. ALLAN MCLANE HAMILTON related some experiments with muscarine, which is the active principle of the agaricus muscarius, one of the poisonous fungi. This fungus is of the large orange-red variety, mottled with white warts. His experiments were few in number, but in the main substantiated what Brunton had said. It paralyzed the heart, and seemed to have a special action upon involuntary muscular fibre. Dr. H. was engaged in experiments upon the warm-blooded animals, and expected at a future time to inform the Society as to his results.

DR. DUPUY called attention to the labors of Prevost, who had anticipated Brunton; he also alluded to the counteraction of atropia.

DR. SWEEZY had used muscarine in posterior spinal sclerosis, and considered that it had the property of abating the severe pain in the limbs, which was an early symptom of that disease.

DR. J. J. MASON related a case of a patient who lost consciousness from one to six times daily. He had a convulsive movement of the diaphragm, which was connected with epigastric pain. The pupils were alternately contracted and dilated during the attacks, and the temperature ranged from 100° to 102° F. There was a tender point over the spine, which, when touched by the electric brush, was followed sometimes by an attack. The attacks began by clonic spasms and ended in rigidity, and sometimes opisthotonos. There

was no loss of consciousness. Has passed 160 ounces of clear urine in twenty-four hours. The actual cautery had improved the patient's condition. Dr. Mason considered the case one of male hysteria. Out of 204 cases of hysteria observed by Briquet, 11 were men.

Dr. Dupuy, who had seen the man in an attack, heard a cry which was almost identical with that expressed by hysterical women. He thought that there was no reason to suppose that the patient was a malingerer, and thought the sustained spasm of the diaphragm could not be feigned.

Dr. Newman inquired whether there was heart trouble in the case.

Dr. Mason replied that there was none.

Dr. Dupuy then called the attention of the Society to a phenomenon he had observed in electro-physiology. When the exposed nerve in a galvanoscopic frog was laid in a drop of water upon a piece of rubber cloth, and the water touched by the point of a pair of forceps held in the hand of the experimenter, a convulsion would follow. This would not recur if glass plate was substituted for the rubber, nor if the blunt end of the forceps was applied.

Dr. Mason thought that friction made upon the rubber would generate static electricity enough to account for the phenomenon.

Dr. Hamilton thought that a current might be developed between the metallic element of the prepared rubber and the metal point of the forceps, which would be sufficient.

The Society then adjourned.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 5 to November 11, 1876.

Clements, B. A., Surgeon. To re-join his station at Fort Sanders without delay. S. O. 146, Dept. of the Platte, Oct. 30, 1876.

Forwood, Wm. H., Surgeon. Assigned to duty, temporarily, in office of the Medical Director of the Department. S. O. 165, Dept. of the South, Nov. 4, 1876.

DeGraw, C. S., Asst. Surgeon. Granted leave of absence for four months. S. O. 231, A. G. O., Nov. 4, 1876.

Hall, J. D., Asst. Surgeon. Assigned to temporary duty at Summerville, S. C. S. O. 164, Dept. of the South, Nov. 4, 1876.

Medical Items and News.

Influence of the Age of the Mother on the Sex of the Child.—In the Obstetrical Hospital of Munich, between June 1, 1859, and December 31, 1875, there were 13,469 cases of labor, with 13,621 births. Of these children, 7,021 were males, and 6,600 females, the proportion being 106.4 : 100. Dr. Hecker, who classified these cases, found that 432 primiparæ, who had passed their 30th year, were delivered of 247 male and 185 female children, the proportion being 133 : 100. The doctor thinks that the age of the mothers had some influence in deciding the sex of the children. Other observers had previously obtained similar results. Thus Ahlfeld found that of 102 children whose mothers were primiparæ over 30 years of age, 59 were boys and 43 girls, a proportion of 137 : 100. Schramm collated the cases of 599 primiparæ over 30 years of age, who were delivered of 348 boys and 262 girls, being a proportion of 132.8 : 100. In the cases classified by Dr. Hecker, the age of the father did not seem to exert any influence on the sex of the child. Ahlfeld thought that there are male and female ova in the ovaries, but if so, it would be difficult to account for the fact that more males than female ova are matured in women who do not become pregnant until they have reached 30 years of age.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending November 4, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Nov. 4	0	17	31	1	17	40	2
" 11	0	18	53	4	12	47	5

Dr. J. A. Octerlony, of Louisville, has resigned his professorship of materia medica in the Louisville Medical College and the Kentucky School of Medicine. This is a great loss to the double-headed school.

Seguin's Prescription Book.—We are surprised to notice that Messrs. J. B. Baillière & Son, of Paris, have republished the useful Pocket Prescription Book of Dr. E. Seguin, of this city, and that they have entirely ignored the authorship and omitted his name. If it is true, as we have heard, that Dr. Seguin freely offered the work to these publishers, it is indeed more than strange that they should have acted as they did. As the publishers call for suggestions tending to improve their edition, we would suggest one that occurs to us as a very important one, and that is, to put the name of the real author upon the title-page.

Brigham Hall, Canandaigua, N. Y.—Dr. Dwight R. Burrell, for several years Assistant Physician to Bloomingdale Asylum for the Insane, has been appointed Resident Physician of Brigham Hall.

Wisconsin State Board of Health.—Wisconsin has created a new State Board of Health, and the Governor has appointed the following gentlemen as members of said board: Drs. O. G. Selden, Reedsburg, one year; H. P. Strong, Beloit, two years; J. T. Reeve, Appleton, three years; Gen. James Bintliff, Janesville, four years; Dr. Solon Marks, Milwaukee, five years; Dr. John Favill, Madison, six years; and Dr. E. L. Griffin, Fond du Lac, seven years. At the first meeting of the Board Dr. E. L. Griffin was elected President, and Dr. J. T. Reeve, Secretary.

Toothache.—Dr. D. Duckworth (Practitioner) cures toothache by an application of solution of bicarbonate of soda (ʒ ss. to ʒ i. of water), after other remedies failed.

Infectious Disease.—The Montreal City Corporation have proposed a new by-law, to the effect that a fine of forty dollars and two months' imprisonment shall be imposed upon any practitioner neglecting to report to the Health Committee any case of infectious disease within twelve hours after its occurrence. The profession in that city is very much opposed to the measure.

Original Lectures.

LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

LECTURE V.

TYPHOID FEVER (CONTINUED).—PROGNOSIS.

GENTLEMEN:—I have already spoken to you of the differential diagnosis of typhoid fever, and will now give you some of the more prominent rules which should govern you in its prognosis.

Prognosis.—Death may occur at any stage of typhoid fever. A typhoid patient is not out of danger until all tympanites, diarrhœa, and other abdominal symptoms, which indicate that intestinal changes are still progressing, have disappeared. Independent of complications, the duration, type, and intensity of the febrile excitement has more to do than all the other elements in determining the prognosis in any case of typhoid fever. The height of the temperature on the eighth day determines the range of temperature that may be expected on each succeeding day. If upon that day it is not higher than 104° F. or 105° F., and has been regular in its development (independent of complications), the prognosis is good; in uncomplicated cases it very rarely rises higher than the degree it has reached at that time. A prolonged high temperature (above 105° F.) after the first week renders the prognosis unfavorable.

In mild cases, during the second week a marked morning remission occurs, which begins early and continues until midday; the evening exacerbation is late, and by the end of the second week there is a marked and permanent fall in the temperature. In severe cases, the opposite conditions are observed. A sudden rise in temperature, or a rapid and extreme fall at any period of the fever, is a very bad omen; the latter often precedes the occurrence of a severe intestinal hemorrhage. Marked variations from the typical temperature of the disease indicates the existence of complications. Slight decline, accompanied by great fluctuation of temperature, during the third week, is an unfavorable symptom. The natural power of an individual to resist disease, especially the effects of prolonged high temperature, is a very important element in prognosis. The organ which is the surest indicator of such power (especially in typhoid fever), is the heart. If the pulse is full and regular, perhaps beating at the rate of 110 or 115 per minute, if the cardiac impulse is good, and a distinct first sound can be heard, even though at the end of the second week the temperature stands as high as 106° F., the prognosis is favorable. If, however, the pulse has risen to 120 or 130 per minute, if the apex beat is feeble or imperceptible, and the first sound of the heart is indistinct or altogether obscure, with a tendency to cyanosis and pulmonary œdema, the indications are that the patient's powers of resistance are failing, and under such circumstances the prognosis must be unfavorable. It is not so much the rapidity, as the regularity, a sudden falling and a sudden rising of the pulse, that indicates the impending danger. The rapid rising of the pulse upon the slightest excitement is the most unfavorable indication, as it shows extensive heart-failure and a rapid giving way of vital power.

Age.—The influence of age is very great in determining the prognosis in any case of typhoid fever.

The prognosis is much better in children than in adults. Occurring in persons over forty years of age, the prognosis is decidedly unfavorable, even though the symptoms may not indicate a severe type of the disease.

In the case of those individuals who habitually use alcoholic stimulants, whose powers of resistance to high temperature is diminished, the rate of mortality is very great.

The puerperal state renders your prognosis especially unfavorable. The danger to the patient is equally great, whether the fever comes on prior to delivery or during puerperal convalescence.

In this fever there is greater danger to those who are suffering from any form of chronic disease, than to those who are in a healthy condition at the time of the attack.

The complications which influence prognosis are more numerous than those in any other disease.

I shall briefly allude to those which are intimately connected with, or dependent upon, the morbid changes ordinarily incident to the disease, and afterward speak of those which may be designated as accidental complications.

The parenchymatous changes which take place in the different organs of the body, during the progress of this fever, necessarily influence prognosis. For instance, the muscular degenerations of the cardiac walls and the consequent loss of heart-power, which favors pulmonary and other hypostatic congestions, and the diminished quantity of blood sent to the various tissues of the body, interfere more or less with their nutrition. Necrotic and gangrenous processes, sometimes met with in the cellular tissues of the surface, and along the line of the intestines, also the venous thrombi which so frequently develop in a protracted case of this fever, are, to a certain extent, the result of this cardiac weakness. It is apparent that the development of extensive cardiac degenerations must render the prognosis unfavorable.

Excessive cardiac weakness favors the development of blood-clots in the heart cavities; these may break up and cause embolism somewhere in the course of the general circulation, and thus lead to changes which may destroy life. Again, intestinal perforations, one of the results of the intestinal changes incident to the fever, render the prognosis most unfavorable. The same is true of copious intestinal hemorrhages coming on after the third week of the fever, as well as of all those glandular changes which are a part of the natural history of the fever, and which I have already described.

Any of these changes may lead to complications which endanger the life of the patient, and consequently when they occur, necessitate a guarded, if not an unfavorable prognosis.

Some of the prominent accidental complications which may occur in the course of typhoid fever, but which do not belong to its regular history, have their seat in the respiratory organs. Slight bronchial catarrh is present in nearly every case, and can hardly be regarded as a complication. It is so much a part of the clinical history of the disease, that some have named this fever bronchial typhus. There is another much more serious bronchial complication, namely, catarrh of the smaller bronchi, or capillary bronchitis. This usually comes on during the second or third week of the disease, and if extensive, greatly endangers the life of the patient. If then during this period of the fever you have sub-crepitant râles suddenly developed

over the whole of both lungs, accompanied by great dyspnœa and an abundant expectoration of stringy mucus, you are warranted in giving an unfavorable prognosis.

Extensive œdema of the lungs occurring with, or independent of, capillary bronchitis and pulmonary congestion, sometimes comes on suddenly during the third week of typhoid fever, and indicates great failure of heart-power. The slightest indication of its occurrence should always be regarded with suspicion. It is not unfrequently accompanied by more or less extensive hemorrhagic infarctions of the lungs; these depend on embolism of some of the branches of the pulmonary artery due to fragments of clots which have formed in the right side of the heart, the result of the cardiac weakness. They often lead to gangrene of the lung. It is sometimes impossible to diagnosticate their existence during life.

Pneumonia, when it complicates typhoid fever, is generally latent. It comes on very insidiously, and unless you are on the watch for its development, and make frequent and careful physical examinations, it will pass unrecognized. It is more frequently developed during the third and fourth week of the fever, and usually is catarrhal rather than croupous in character. At first only single lobules are involved, but after a time an entire lobe becomes consolidated. When irregular variations in temperature occur during convalescence, or during the third or fourth week of the fever, there is reason to suspect the development of pneumonia. In the majority of cases the characteristic pneumonic cough and expectoration are absent. Whenever an extensive pneumonia complicates typhoid fever, the prognosis is especially unfavorable.

Pleurisy does not occur so frequently as a complication of typhoid fever, as does pneumonia or bronchitis. When it does occur, pus is almost invariably the product of the inflammatory process. Usually it comes on late in the disease, comes on insidiously, and is quite likely to pass unrecognized unless frequent physical examinations of the chest are made. In many instances it is really a sequela of the fever, not developing until three or four weeks after the fever has run its course. Its occurrence must always be regarded as unfavorable; for a year or even longer time must elapse before recovery can take place, and even then recovery is doubtful.

Occasionally, laryngitis is a serious complication of this fever. It generally occurs in those cases where the fever has been very protracted, and there is great prostration. Its presence is marked by sudden and very intense inflammation of the mucous membrane of the glottis, which is liable to become œdematous, when death may suddenly occur. It may lead to ulceration of the mucous membrane. Whenever, during any stage of a typhoid fever, the characteristic symptoms of laryngeal obstruction occur, remember the danger of œdema glottidis and of extensive laryngeal ulceration, and promptly resort to those means which shall relieve the unpleasant symptoms, and avert the danger which threatens your patient.

Pyæmia may be met with as a complication during convalescence from typhoid fever, but it is not of as frequent occurrence as septicæmia. Whenever we have septic poisoning developed, with extensive sloughs in the intestines, the prognosis is exceedingly unfavorable.

Acute gastric catarrh is another complication of this fever, the possible occurrence of which must enter into your prognosis. A patient may have reached his fourth week, and be rapidly convalescing, his desire for food returning; you endeavor to hasten his recovery by increasing the quantity of food taken, or by allowing him to partake freely of such articles of food as are difficult of digestion. The result of this overcrowding, or of imprudence in diet, is irritation and inflammation of the enfeebled gastric mucous membrane. Vomiting of a stringy mucus occurs, which by its prostrating effects endangers or destroys the life of your already enfeebled patient. I would impress you with the importance of exercising the greatest care in regard to the diet of patients convalescing from typhoid fever. They should be restricted to milk and nutritious broths in moderate quantity until all danger from this complication shall have passed.

Disturbances of nerve function have been considered under the head of symptoms, but, not unfrequently, certain brain and nerve lesions are developed, which cannot be classed under that head.

Cerebral œdema may complicate a typhoid fever during its third week, and give rise to symptoms of a grave character. A decided enfeebling of the mental powers, and a tendency to stupor, announces its occurrence.

Hemorrhagic extravasations on the surface, and into the substance of the brain, the result of degeneration of the walls of the cerebral vessels, occasionally occurs during the height of the fever. If the effusion is moderate, no marked symptoms are developed, but if a considerable extravasation takes place, it gives rise to symptoms of cerebral compression.

Meningeal inflammation is a rare complication.

The occurrence of any of these complications in any case renders the prognosis unfavorable.

You must remember that during the second or third week of the fever certain cerebral disturbances may occur, which seem to indicate the existence of some one of these complications, when really no cerebral lesion exists. Usually, these are present in patients who have had a continuously high temperature; in favorable cases they disappear after a few days. These have been referred to under the head of symptoms.

You will encounter various other disturbances of the nervous system, such as hemiplegia, paraplegia, etc., which may simulate those due to lesions of nerve centres, or local forms of paralysis and anæsthesia, which seem to be confined to individual nerves; but as these functional disturbances do not depend upon any anatomical changes, the prognosis in such cases is good.

Those changes in the kidney which are due to the parenchymatous degeneration which usually attends this fever, have been already noticed; but occasionally nephritis is developed as a sequela. The urine becomes scanty, is loaded with albumen, and contains blood and casts; the face and extremities become œdematous, and death may occur from uræmia. The occurrence of this complication necessarily renders the prognosis bad.

In a few instances under my observation, severe catarrh of the bladder had developed during convalescence, greatly complicating the case; in one instance the cystitis was accompanied by pyelitis.

Suppurative inflammation of the cellular tissue of the body, or cellulitis, especially of the surface, often complicates convalescence, and in some cases causes death. It is most liable to develop in those parts which have been subjected to long-continued pressure. Occasionally it is met with in the pharynx, and along the line of the lymphatics.

Accompanying these cellular inflammations, or occurring independently of them, not unfrequently gangrenous inflammations of the integument occurs,

giving rise to what has been called *bed-sores*. These gangrenous processes are most frequently developed at those points which have been subjected to the greatest pressure, on account of the position of the patient, such as the sacrum, nates, heels and shoulder-blades, etc. In the simplest form of *bed-sores* there is only a superficial loss of substance; in more severe cases the subcutaneous cellular tissue is involved; and in the worst cases the muscles and fibrous tissues. I have met with cases where the slough had involved the connective tissue and muscles, and laid bare the bony tissue.

A considerable number of typhoid patients who have lived through the fever, die either from the exhausting effects of these bed-sores, or from the septic poisoning resulting therefrom.

The possible occurrence of these complications must enter into the prognosis in every severe case, and the earlier they make their appearance the greater the danger.

We have now completed the list of principal complications which are to modify your prognosis in any case of typhoid fever. Before leaving the subject, I will say a word in regard to the *duration* and *mode* of termination of this fever.

Its average duration is from three to four weeks; a typical case extends over a period of four weeks. When the fever is protracted beyond the middle of the fourth week, in most instances this is due to some complication or to an extension of the intestinal ulceration. The period of greatest danger is at the close of the third week. Death rarely occurs before the fourteenth day. The prominent direct causes of death are: 1st. Toxæmia; 2d. Asthenia; 3d. Suppression of the excretory function of the kidneys; 4th. Hyperæmia and œdema of the lungs; 5th. Intestinal hæmorrhage; 6th. Exhaustive diarrhœa; 7th. Intestinal perforation; 8th. Peritonitis, with or without intestinal perforation. In nearly all cases the failure of heart-power is directly or indirectly the cause of death.

Relapses.—After typhoid fever has run its course, and after the patient is entirely free from fever, quite frequently we have a new development of the fever; these developments are called relapses. Their course corresponds with that of the primary attack, only they are of shorter duration. The temperature rises more rapidly, the eruption reappears, the spleen enlarges, the intestinal and abdominal symptoms return, and all the prominent symptoms of the primary fever are rapidly developed. As a rule, the relapse is milder than the primary attack. If it terminate fatally the post-mortem examination shows, in addition to the cicatrizing intestinal ulcers of the primary attack, the recent intestinal changes of the relapse. The lesions of the relapse, although of the same character as those of the primary attack, are less extensive.

It is very difficult to give a satisfactory explanation of these relapses. Some claim that they are the result of certain plans of treatment, especially the cold-water plan. This assertion lacks proof. Again, others hold that all relapses depend upon a new infection. Perhaps this is possible if the patient remain in the same locality and has the same surroundings as when he had the primary attack; but how shall we explain relapses in those who are removed from all the sources of the primary infection? Another explanation offered is, that a part of the typhoid poison has remained in the system, undeveloped during the primary attack, and that some time after this has passed the poison reproduces itself and sets up a second fever.

A more recent theory is, that the typhoid poison thrown off in the fæces of the patient is reabsorbed and causes the relapse. Unquestionably, it is possible for healthy glands to become inoculated by sloughs thrown off from those first affected.

In many cases it is impossible to account for the occurrence of the relapse, and all of these explanations as to the cause in any case are more or less unsatisfactory.

In those cases which have come under my own observation, I have noticed that the splenic enlargement which has existed during the course of the fever does not subside with its decline; and that the tenderness along the line of the intestines, especially in the right iliac region, continues during the period between the original attack and the relapse. In some instances, apparently, the relapse has been brought on by indiscretion in diet, or by injudicious exercise on the part of the convalescent patient. Occasionally relapses have occurred when great care had been taken against any indiscretion or over-exertion.

CASES BEARING ON SOME DOUBTFUL POINTS IN THE HISTORY OF SYPHILIS.

By R. OSGOOD MASON, M.D.

NEW YORK.

THE RECORD of Oct. 21st ult., under the head of "Progress of Medical Science," gives the results of certain observations by M. Diday concerning the syphilitic infection of the mother through the fœtus.

It is well known that amongst specialists and teachers in this branch of medical science the possibility of such infection has, to say the least, been looked upon with doubt and disfavor. M. Diday's investigations in this direction, however, have led him to the conclusion that "the child begotten by a syphilitic father, without actual lesions, may infect the mother at any period of its intra-uterine life," either as ovule, embryo, or fœtus. At the time the item above referred to came to my notice, I had under observation the following case:

Mrs. A., æt. thirty years, and three years married, was at the time of her marriage an unusually strong, robust, and healthy looking woman. Soon after marriage she became pregnant and miscarried at 4½ months, with a fœtus of about three months' development, on which occasion I first attended her. After some months she again became pregnant, and was delivered at term. I did not see her during this pregnancy nor at the confinement. I know, however, that she had a most miserable recovery, which was impeded by most distressing and obstinate mammary abscesses, and followed by general ill-health. I was called to see the child when it was six months old; it was then moribund, and died the following morning of exhaustion, partly from diarrhœa, but especially from a number of large blebs or superficial abscesses situated mostly about the head, and containing an abundance of thin, sanious pus.

I saw no more of the family for several months, until in September last I was again called to attend Mrs. A. for dysentery already of a week's duration. It yielded somewhat to rest and opium treatment; it would not, however, remain under control, but gradually changed its character to a thin, dark diarrhœal discharge, always worse at night, which continued, notwithstanding my best endeavors, for full

five weeks, during which time I also ascertained that she was two months or more pregnant.

At this time (Oct. 17th) Mr. A., the husband, was taken ill with symptoms of meningitis. He had a pulse of 64, partial paralysis of the right side, and stupor, from which he was aroused with considerable difficulty, when he would just recognize those about him, answer some simple question, and immediately fall off again to sleep.

Mr. A. had been my patient for many years, and his previous history has a peculiar bearing upon his own case, as well as that of his wife. Twelve years ago he contracted syphilis, was thoroughly treated and apparently cured. Two years later the disease again made its appearance in the form of nocturnal headaches and gummy tumors about the elbows. He was then treated with large doses of iodide of potash, and made a prompt recovery, though treatment was continued for some months.

He was at that time a married man, and was the father of healthy children. After recovery from this attack his wife again became pregnant, and was delivered of a healthy child, which is still alive and apparently wholly free from syphilitic taint.

Soon after this the wife died of tubercular disease, and a second marriage was contracted, the results of which have already been given. They sum up as follows:

1st. A miscarriage, attended with symptoms of a suspicious character.

2d. A syphilitic child, followed by unusually severe and obstinate mammary abscesses and failing health.

3d. A pregnancy which in the second month is accompanied by syphilitic symptoms on the part of the mother, at the same time that symptoms reappear in a dangerous form in the father.

The illness of Mr. A. at once cleared up the whole case, and the diarrhœa, which had resisted five weeks of thorough ordinary treatment, with the advantage of rest and care, yielded in six days to two grains of blue mass, given four times a day, while going about and attending upon her husband.

Mr. A. also rapidly recovered under the use of large doses of iodide of potash and mercurial inunctions. By large doses of pot. iod. is meant a drachm every four hours, or, perhaps still better, half that quantity every two hours, until decided iodism, as indicated by the breath, is produced, and the same repeated at proper intervals afterwards.

I am also kindly permitted by my friend Dr. Loomis, of this city, to refer to the following case, which came under his observation, and which, if possible, is still more definite and cogent in its bearing.

Eighteen years ago a young man, then recently treated by the Doctor for syphilis, both primary and secondary, came again for advice concerning marriage, and was advised to delay. Soon after, however, he took counsel of his inclinations and married a young and perfectly healthy wife. In the course of the next five years two healthy children were born, both of whom are still alive and apparently free from any syphilitic taint. The next pregnancy terminated in a miscarriage, with a syphilitic fœtus. At this time the husband had a return of secondary symptoms, and soon after the wife was attacked with syphilitic rheumatism and sore throat. These yielded to appropriate treatment, and pregnancy again occurred, but terminated also in a miscarriage, and was soon after followed by periostitis and suppurative nodes. Treatment again caused a disappearance of the symptoms and return to health, and for several years no returning symptoms manifested themselves. Two years ago, however, she was again attacked, this time the disease assuming the form of pachymeningitis, with most alarming symptoms—paralysis, stupor, and even decided coma, continuing several days, and followed by delirium and dementia. This case also yielded to the large doses of iodide of potash, and resulted in a slow and only fair recovery.

An important and, in fact, the main question in both these cases is, how did the mothers contract syphilis—by primary infection or through pregnancy? And in answer I would submit the following considerations:

1st. Both the fathers were treated by the physicians respectively reporting the cases, and were known to have had syphilis in both its primary and secondary forms, thus rendering a second primary infection, to say the least, very improbable, if not impossible. Besides, each father was under the care of these physicians from the time of the first infection until the time when syphilis was developed in the mother, and no second infection occurred.

2d. The character and social position of both mothers, well known to their respective physicians, are sufficient guarantee that infection did not take place from persons other than their own husbands; and, besides, no such primary lesion is known or suspected by their medical attendants to have existed.

3d. Syphilitic symptoms did not occur until after pregnancy, but were developed during pregnancy or very soon after; leaving, as it seems to me, no fair conclusion but that the infection was a direct result of pregnancy.

It is worthy of remark in both these cases that decided syphilitic symptoms first showed themselves in the mother at or about the same time that symptoms of returning disease manifested themselves in the father.

As a last important and curious consideration, I would call attention to the fact that healthy children, still living under observation, and still free from any manifestation of syphilitic disease, were begotten by both these fathers after they had developed and been treated for secondary syphilis; and then, subsequently, without any new infection, they have begotten children through whom, and during whose intrauterine life syphilis was communicated to the mothers.

No. 123 W. 21st Street New York, Nov. 8, 1876.

THE TREATMENT OF TETANUS BY CALABAR BEAN.

By LEWIS A. STIMSON, M.D.,

one of the surgeons to the presbyterian hospital, N. Y.

During the last four years the calabar bean has been recommended as a cure for tetanus. Gubler, the latest (1874) French writer on materia medica, mentions a dozen cures of traumatic tetanus by it (some of them questionable), as against four reported failures. Wood gives forty-seven cases (variety not mentioned), with twenty-seven recoveries, and twelve cases of traumatic tetanus with five recoveries; and recently the *Lancet* has published three cases, two traumatic, one idiopathic, of which one of the former and the latter recovered. As it is essential to a proper appreciation of the therapeutical value of the agent that the failures should be reported as well as the successes, I send you the following notes of a case that came under my observation.

Hoffmann, twenty-one years old, unmarried, machinist, was admitted to the Presbyterian Hospital, 14th Oct., 1876. Four days before admission his left hand had been injured in a railway accident. There was compound fracture of the first phalange of the middle finger, the flexor tendons of the ring-finger were entirely exposed, and the ulnar half of the same finger was gangrenous. The patient consented to have the ring-finger removed, but insisted that an attempt should be made to save the other. On the 15th Oct. I removed the third finger under the carbolic spray, and dressed the wounds antiseptically. The dressing was renewed the next day (16th), and again on the 18th, the patient's temperature being then 100¼. The wounds looked well; no swelling, redness, or pain in hand or arm; suppuration slight. On the morning of the 19th the patient complained of inability to open his mouth freely. When I saw him in the afternoon the masseters were contracted; the jaw could be moved, but not opened as widely as usual. Appetite good. Ordered chloral gr. xxx. every six hours. Oct. 20th, 2 P.M., I found the patient restless, and covered with perspiration; temperature 101°, pulse 146, pupils slightly dilated and responding promptly to changes in the light; the muscles of the back of the neck and the sterno-cleido mastoids rigid; the lower jaw could be moved only one-quarter inch; the head and neck could not be flexed or rotated; all other muscles relaxed. Heart and lungs normal. Bowels had moved freely the previous evening. Ordered the chloral to be discontinued and the extract of calabar bean administered hypodermically every hour in increasing doses, beginning with one-third of a grain—brandy, beef-tea, and milk. Owing to some difficulty in obtaining the drug the first dose was not given until 7.15 P.M.

The following notes are taken from the record made at the time by the house-surgeon, Dr. Van Houten, who spent the entire night at the bedside of the patient.

6 P.M. Marked contraction of sterno-cleido mastoid, trapezius, masseter, and buccinator; profuse perspiration; complains of pain in the region of the lower cervical and upper dorsal vertebræ. 7.15 P.M. One-sixth gr. of extr. of calabar bean injected into the substance of each trapezius muscle. Pulse 146. Temp. 100°. Resp. 31. Pupils dilated. 8.15 P.M. One-third gr. cal. bean. Temp. 99°. General slight rigidity. Thighs flexed in abdomen. Complains of shortness of breath. Distressing thirst. 9.15 P.M. Breathing spasmodic, sense of suffocation. Rigidity more marked. Temp. 100¼°. Pulse 146. Injected one-third gr. 10.15 P.M. Injected one-half gr. Resp. 48, quick and labored; pulse 150. Rigidity, perspiration, and thirst continue. Patient has taken large quantities of the brandy and milk mixture. Pupils are dilated and respond to the light. 11.15 P.M. Injected one-half gr. Frequently recurring spasms, lasting for a few seconds, especially in legs and thighs.

Oct. 21st, 12.15 A.M. Injected three-quarter gr. Spasms more violent. Pain in epigastrium, abdominal muscles very tense. Other symptoms unchanged. 1.15 A.M. Injected three-quarter gr. No change. 2.15 A.M. Gave three-quarter gr. of cal. bean by mouth. Pupils slightly contracted and do not respond. Mouth can be opened a little wider, less perspiration, muscles less rigid, occasional spasms. 3.15 A.M. One gr. cal. bean by mouth. Muscles rather less rigid, occasional spasms. 4.15 A.M. One gr. cal. bean by mouth. No change. Resp. 52. Pulse 144. 6.15 A.M. One gr. cal. bean by mouth. Pupils dilated and respond. Patient sits up in bed and breathes more easily in consequence. Has not slept at all. 7.15 A.M. Injected one-half gr. Pupils not so much dilated. 8.15 A.M. Injected one-half gr. 9.15 A.M. Two-thirds gr. Respiration 46 and very labored; pulse 146; some spasms of the muscles of deglutition. 10.15 A.M. Injected one gr. No improvement in the breathing. Attempts to drink bring on spasms. Legs slightly rigid. 11.15 A.M. All the symptoms aggravated. Pupils contracted. Perspiration profuse. Injected fifteen minims of Magendie's sol., and made patient inhale chloroform.

12.15 P.M. Less restless. Temperature in axilla 102°. Injected 1½ gr. calabar bean. 1.40 P.M. Injected 15 ♏ Magendie. Patient can open his mouth quite freely; abdominal muscles and legs relaxed.

[At half-past 2 P.M. I saw the patient and found him breathing with much difficulty. None of his muscles were contracted, but every few seconds his inspirations were cut short by spasmodic contraction of the abdominal muscles, the air being driven forcibly out of the lungs. The muscles of the back and the intercostal muscles were included in the spasms. His countenance was livid, and the skin covered with perspiration. During each interval he fell into a doze and was evidently suffering greatly for want of sleep. A few inhalations of chloroform put him to sleep and stopped the spasms. The lividity of the lips gave place to a bright color, and I left him at three o'clock sleeping quietly, with instructions to have the condition maintained by means of chloroform if necessary, for four or five hours.]

5.30 P.M. Still sleeping; temperature 103°. Pulse 152; skin hot and dry, except upon the forehead. The slightest touch of the bed-clothing causes a spasm. 7 P.M. Injected one gr. calabar bean. Muscles are relaxed. He urinates frequently. The slightest touch causes a spasm. 8 P.M. Chloroform discontinued. Pupils contracted, respirations 52; pulse 148. Muscles relaxed; occasional spasms. 9.30 P.M. Patient has just had a general tonic spasm lasting about thirty seconds, more marked in the lower extremities. Cold perspiration; pulse 156, resp. 44. Tongue was badly bitten during the spasm. 9.45 P.M. Left pleurosthotonos. After the convulsion the pulse was so feeble that it could not be counted. Injected ℥ss. brandy. 10 P.M. Pulse 64. An attempt to drink caused a convulsion with right pleurosthotonos. Finger-nails blue, face cyanotic. 10.12 P.M. Another tonic spasm. Pupils rather larger. 10.15 P.M. Another convulsion; cyanosis; death

Post-mortem examination showed intense congestion of the envelopes of the brain and spinal cord. The heart was enlarged; there were signs of a recent slight adhesive pleurisy. The kidneys were large, hard, and (like the other abdominal viscera) greatly congested.

The points in this case to which I would call attention are, that although the patient's condition improved at first after he had taken 6¼ grains of the extract of calabar bean in ten hourly doses, the improvement was not maintained although full doses of the drug (½ to 1½ gr.) were given frequently; and secondly, that the respiratory trouble was due to spasm of the muscles of expiration and not to spasm of the diaphragm. The inspiratory movement was arrested suddenly and the air violently expelled.

The physiological effect of the calabar bean, although evident, was at no time very marked, and it is possible that the preparation had deteriorated by keeping. While the promptness with which the drug deteriorates may explain its failure in this and other cases, it is none the less a legitimate objection to its employment under circumstances where any lack of power on its part will prove fatal.

ATTACHMENT OF THE APPENDIX VERMIFORMIS TO THE POSTERIOR PART OF THE ABDOMINAL CAVITY, FORMING A LOOP.

EIGHTEEN INCHES OF SMALL INTESTINE CROWDED THROUGH THIS LOOP.—STRANGULATION AND DEATH.

By H. W. HENDRICKS, M.D.,

HYDE PARK, VT.

On the morning of September 17th I was called to see A. C., aged twenty-five years, who I was informed had been suffering from severe colic for about four hours. On arriving at the house, I found the man suffering severe pain in the region of the umbilicus, but having neither fever nor tenderness about the bowels. I gave him a few drops of chloroform and a hypodermic injection of morphia, which quickly relieved nearly all of the pain. I then gave directions to use no cathartic, but to move the bowels with enemas. After using several of these with no good results, we decided, as there was very little pain, to try some mild laxative. Accordingly a dose of castor-oil was given, which was retained on the stomach for about three hours, when it was vomited. This seemed to increase the pain and vomiting somewhat, and as twenty hours had elapsed since my first arrival, with no movement from the bowels, and the patient suffering severe pain at this time, I asked for counsel. Dr. Randell was called on the morning of the 18th of September. His desire was to try the treatment for inflammation of the bowels—calomel and opium. This treatment was continued for forty-eight hours, when the pain and tenderness were very much allayed. At this stage, three days after the first attack, as the patient was quite free from pain, with very little irritability of the stomach, we again tried to move the bowels with vegetable cathartics and enemas. The bowels moved a little twice, but the cathartics caused some sickness at the stomach. During the first six days the pulse was good; the stomach not very irritable, but some tympanites about the bowels; also some tenderness. On the seventh day the pulse suddenly became feeble, and the extremities began to grow cold.

At this stage Dr. Hall was called in. He advised an enema of mucilage and croton oil, which was tried with no effect; also a large dose of calomel was given, with like result. The patient continued to fail notwithstanding stimulants were freely used, and died at the end of the eighth day.

Autopsy twelve hours after death.—Decomposition fast taking place. Bowels considerably distended with gas. Peritoneum somewhat inflamed. Stomach nearly empty. Small intestines filled with gas. Large intestines empty. The appendix vermiformis was drawn across the bowel at the junction of the ileum and cæcum, and attached to the posterior wall of the abdomen, a little to the right of the spine, forming a loop about six inches in circumference. Through this loop about eighteen inches of small intestine was crowded, and this plainly showed the cause of the colic from which the patient suffered at first; also the cause of the inflammation of which he finally died. I omitted to mention one thing in the treatment, which was attaching to the nozzle of a syringe a flexible tube fourteen inches long, and introducing it into the rectum and colon, and giving enemas through this.

Dr. Brown-Séquard is advertised in *The Lancet* as intending to resume practice in London.

Progress of Medical Science.

Gastrotomy and Gastrostomy.—Dr. J. H. Pooley, of Columbus, Ohio, in a very complete article written upon this subject, published in the early part of the summer, defines gastrotomy to be the opening of the stomach for the removal of foreign bodies which have been swallowed accidentally or intentionally, and which by their bulk or form are not liable to pass through the intestines and be discharged per anum, or got rid of by vomiting, or which give rise to immediately severe symptoms. Gastrostomy he defines to be an opening made directly into the stomach, and the establishment of a permanent fistula for the introduction of nourishment in cases of inveterate stricture of the œsophagus, whether from cancer, the cicatricial narrowing following the ingestion of scalding or corrosive liquids, or from any cause where death threatens, and life may be prolonged. He mentions two cases of accidental gastrotomy taken from *Turner's Surgery*, published in 1736, and quoted from older sources, one as far back as January, 1632. A table is then given of eleven cases of gastrotomy performed for the removal of foreign bodies, dating from 1613 up to 1856. All but one of these cases recovered. He also gives a similarly arranged table of eighteen cases of gastrostomy, performed for stricture of the œsophagus, from 1849 to 1872. The result in all these cases was death. He does not think this necessarily proves the operation is always to be unsuccessful. Mr. Bryant's views are his own, when he says one cause of the failures thus far has been the putting off the operation until so late a period. It may turn out to be a parallel operation with colotomy, which was unsuccessful until it was undertaken at an earlier stage of the disease. Dr. Pooley favors Mr. Bryant's operation—that of making an oblique incision along the cartilages of the ribs, and extending pretty high up toward the xyphoid cartilage.

This paper is extremely interesting, in view of the following successful case, of which the history has just reached us:

A Successful Case of Gastrostomy.—At the meeting of the *Académie de Médecine*, in Paris, on October 24th, M. Verneuil reported the first really successful case of gastrostomy that has yet been recorded. M. Verneuil stated that the operation had previously been performed fifteen times for simple and malignant strictures of the œsophagus, but had always been followed by death. Dr. Pooley, of Ohio, however, as alluded to above, has collected eighteen cases, in one of which the patient lived thirteen days after the operation. M. Verneuil's patient, a boy seventeen years of age, swallowed by mistake a solution of caustic potash, on February 4, 1876. For two weeks he suffered from the symptoms of an acute œsophagitis, after recovering from which he had great difficulty in swallowing. This difficulty constantly increased, and on May 24th, he was admitted to M. Verneuil's ward at the Pitié. He was then exceedingly emaciated, could scarcely swallow anything, and was almost dying of starvation. Catheterism revealed an impassable stricture, two and three-quarter inches below the upper orifice of the œsophagus. External œsophagotomy was consequently out of the question. The patient was fed per rectum, and futile efforts to pass the stricture were repeatedly made. One day the patient stated that he could swallow a little fluid at night, although deglutition was absolutely impossible

during the day. Convinced by this fact that there was muscular spasm in addition to cicatricial stricture of the œsophagus, M. Verneuil administered to the patient two drachms of chloral per rectum, and as soon as the narcotism was complete, the stomach-tube was passed through the stricture without much difficulty. Although the passage of the catheter caused intense pain, the patient was, for some days afterwards, able to swallow bouillon and pap. The catheterism was repeated every second day, until July 10th, when the stricture again became impassable. The patient after this rapidly became weaker in spite of the nutritive enemata, and finally gastrostomy was determined on, as there was danger of death from inanition. On July 26th, he was placed under the influence of chloroform, and an oblique incision about two inches in length was made parallel to the cartilaginous border of the false ribs. The skin, subcutaneous cellular tissue, muscles, and peritoneum were successively divided, and then the stomach presented itself in the gaping wound. This organ was at once transfixed and held in the wound by two long acupuncture needles, and this was done so rapidly that the abdominal cavity was not exposed to the air for more than fifteen or twenty seconds. Fourteen metallic sutures were then passed through the skin, parietal peritoneum, and wall of the stomach; the sutures were about one-quarter of an inch apart, and were twisted over a tube of lead and a button. The acupuncture needles were then withdrawn, and a small incision made through the wall of the stomach, which had by that time assumed a purplish color in consequence of the constriction by the sutures. The wall was remarkably thick, much more so than it usually is in the cadaver. Two small jets of blood followed the incision, but they were immediately controlled by the application of hemostatic forceps, which were left in position until the evening. The incision was not more than one-third of an inch in extent, just large enough to admit a large gum catheter, which was secured in position by tapes and collodion applied over the abdomen. While applying the sutures the parietal layer of the peritoneum was secured by a dozen or more pairs of hemostatic forceps, which were left on until all the sutures were in place. The operation was exceedingly simple, and was attended by no untoward accident. The antiseptic method was strictly followed, all the instruments, etc., having been steeped in a solution of carbolic acid, and a carbolized spray kept constantly playing on the wound. For some days subsequent to the operation the patient complained of circumscribed pains in the left hypochondrium and right shoulder, and of oppression of breathing from the collodion, and he became jaundiced. There was no fever, however. The sutures fell out spontaneously, and a small portion of the gastric wall, included between the sutures, sloughed so that the opening became larger than at first. The patient was fed through the catheter with bouillon, soups, milk, eggs, wine, etc., etc. On August 20th he was able to get up, and on September 10th the fistula was rounded and encircled by a border of mucous membrane. He had then completely regained his strength and energy. On August 18th he weighed seventy-five pounds, and on September 14th he weighed eighty-six pounds. He experiences hunger and feeds himself with all sorts of food. After injecting this food the flow of saliva is increased, but as the stricture of the œsophagus remains impassable he is obliged to spit it out. It is probable that in course of time the cavity of the œsophagus will be completely obliterated, and the patient will consequently be obliged to feed himself through his gastric fistula during his entire life.—*Gazette Médicale de Paris*, October 28, 1876.

Transmission of Syphilis.—Dr. R. W. Taylor, of this city, states that he has met with four cases in which syphilitic fathers procreated syphilitic children, while the mothers remained healthy. These cases were all most carefully studied, and the doctor thinks that there can be no doubt of the correctness of his conclusions. In several other instances, he was personally satisfied that the fact was the same, but as the cases were not sufficiently complete for publication, he does not take them into consideration. At the present time Dr. Taylor makes public the details of two of the above cases, of which the following is a synopsis. In the first case a man was infected with syphilis a year before his marriage, but under a mercurial treatment of about six weeks' duration all visible manifestations of the disease disappeared, and he stopped treatment. His wife was perfectly healthy and never presented any symptoms of syphilis; but one year after her marriage was delivered at term of a dead child, which presented no perceptible lesions. She subsequently gave birth to four children, all of whom were syphilitic, and all died within a few months of birth. During this time the father was suffering from periosteal pains, ulcers, and a scaly skin affection. In 1866 he sought relief at a dispensary, and was ordered biniodide of mercury and iodide of potassium, which he continued to take for nearly a year, when he became apparently well. In 1867 his wife gave birth to a healthy child which is still living, and never presented any evidences of syphilis. In 1869 the husband again began to suffer from periosteal pains. At this time he impregnated his wife, and she gave birth to an apparently healthy girl. Shortly after birth, however, the child became sick, and was covered with an eruption. She was brought to Dr. Taylor for treatment, and he found the body and extremities covered with a copious roseolous syphilide, with numerous typical syphilitic papules interspersed among the roseolous patches. The papules about the anus were excoriated. There was also intense ozæna. The mother was perfectly healthy. Repeated and most rigid examinations revealed no evidence of syphilis, past or present. Dr. Weir also examined her and pronounced her perfectly free from syphilis, past or present. The father, however, gave a good history of, and presented at the time, many signs of syphilis. The child was treated by inunctions and recovered. The father was put on a mixed treatment (mercury and potash), and the mother was given iron and quinine In 1872 she gave birth to a boy, who was and has since remained perfectly healthy.

In the second case a healthy woman was married to a healthy man in 1862; in the three years following she gave birth to three perfectly healthy children. In 1865 the husband had a chancre, which was followed by a general eruption. He was treated for six weeks, when he considered himself cured. In 1866 his wife gave birth to a boy, who soon became sick, puny, and covered with a skin disease. The history of anal condylomata and ozæna could be made out. In 1869 she had a girl, which soon became sick in the same way as the boy. When the child was four months old it had a squamous, coppery eruption about the mouth, and a roseolous and papular eruption on the body and the soles of the feet. It had also the typical senile facies. At this time the boy born in 1866 had interstitial keratitis, Hutchinson's teeth, and an umbilical hernia. The mother was in blooming health, and the most careful examination failed to reveal any

e vidences of syphilis. In fact, between that time and 1875 she was repeatedly examined, but always with the same result. The husband at that time presented scattered papules on the body, and a gummatous infiltration over the left eye. He was kept under treatment for several months, and in 1872 his wife gave birth to another perfectly healthy child.—*Archives of Clinical Surgery*, September, 1876.

Feeding by the Nose.—Mr. Clement Dukes finds this mode of feeding very useful in mania, delirium tremens, diphtheria, stomatitis, cancrum oris, etc. The apparatus required is one yard of rubber tubing, of one-eighth inch bore, which is to be inserted into a bottle, so that the tube almost reaches the bottom. It works on the syphon principle. The patient lying on his back without a pillow, the tube is exhausted of air and the free end is passed just within the nostril and retained there with the left hand while the right has the tube closed by the pressure of the finger and thumb. Alternate compression and relaxation of the tube allows an ordinary mouthful of the fluid to escape at a time. Mr. Dukes makes use of the same apparatus for washing out the nasal cavities having the head bent forward over a basin.—*The Lancet*, Sept. 16, 1876.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

INTERMITTENT FEVER—CINCHONOIDIN.

Of late several cases of intermittent fever have been treated by the use of cinchonoidin as a substitute for the sulphate of quinine. The size of the doses has been about double that required of quinine, and it cured the disease. It had been thought quite possible that the cinchonoidin produced some irritation of the stomach; at least some nausea, and a burning sensation in the organs had been complained of by the patients while taking the remedy, and had disappeared when the remedy had been discontinued.

DOUBLE QUOTIDIAN INTERMITTENT.

A case of intermittent fever of this form was seen, and it was interesting because of its rare occurrence, and also because it has been claimed to be the only disease, except typhoid fever, that gives a double thermometrical curve in a single day.

UNUSUAL VARIETY OF LATERAL CURVATURE.

The interest in the case, as far as the curvature was concerned, consisted in the fact that the lower portion curved to the *left* and the upper portion to the *right*, which is just contrary to the ordinary form seen in young girls. The patient was a rickety boy aged seven years.

GONORRHŒA—CAUTION REGARDING THE SOURCE OF THE DISEASE IN CERTAIN CASES.

Epitome of History.—A man contracted gonorrhœa; supposed he was entirely cured; subsequently married; within a few days found himself suffering from gonorrhœa again; became frantic regarding the supposed infidelity of the woman he had married; was examined and found to have stricture; was informed that his gonorrhœa was simply relighted from his ancient trouble; became exceedingly anxious then lest he had communicated the disease to his wife; it was communicated to the wife, showing that gonorrhœa may be sub-developed, and that, after it is sub-developed, it has the power to contaminate a healthy individual.

A NEW GUIDE IN THE OPERATION OF EXTERNAL PERINEAL URETHROTOMY.

The case was one in which no instrument could be introduced to serve as a guide to the urethra, so the operator took for his guide the *centre of the pubic arch*. This anatomical point was regarded as a safe guide to the urethra while making the incision in cases in which it became necessary to operate without other aid.

TUBERCULAR MENINGITIS — PHTHISIS — TEMPERATURE NORMAL.

The patient was a young man, æt. twenty years, who had been sick four or five days, and gave the following symptoms: There was marked impairment of the intellectual faculties, the pupils were dilated, and not sensitive to light; there was moderate delirium; the abdomen was retracted; the cerebral patch, that is, the red line developed after drawing the finger across the abdomen, was well marked, the white line enduring *four* seconds and the red line which followed lasting from *two* to *five* minutes. The temperature was normal, and that was interesting from the fact that there were well-marked evidences of phthisis at the apex of the left lung and less marked at the top of the right. The case then illustrated the fact that phthisis might occur without elevation of temperature, and not only that, but that the temperature might remain normal with tubercular meningitis developed in the same patient. The pulse was slow, sixty to seventy, scarcely perceptible, and irregular; a patient near him had heard him complain of headache when first admitted; there was no history of vomiting; he had had hemorrhage from the lungs, three or four ounces, since the meningeal attack; there was marked rigidity of the muscles of the neck; involuntary discharge of urine; but no rigidity of the muscles of the extremities.

The treatment in the case consisted in applying cold to the head; securing a loose movement from the bowels daily, because of the tendency to pulmonary congestion; quieting by the use of morphine, if restless; diminishing cerebral irritability by the use of bromide of potassium in thirty-grain doses every four hours; blister to the nape of the neck; and nourishment, chiefly milk. The question arose, why not give a cathartic? The answer was, that if the case was one of tubercular meningitis, depletion was to be avoided; and besides, the prognosis in these cases was so exceedingly unfavorable it was scarcely worth while to irritate the patient by such procedure.

A PECULIAR ABDOMINAL TUMOR.

The case was one in which the symptoms called for a physical examination of the abdomen. Upon inspection, nothing abnormal was noted. Upon palpation a well-defined tumor, not specially painful upon pressure, could be mapped out at the upper portion of the abdomen and in the median line, somewhat irregular in shape and having a distinct outline, and a feel as though something solid was under the fingers. Upon percussion, however, it was perfectly evident that intestines were beneath the tumor, and the conclusion was reached that the apparent tumor was in the abdominal walls and not in the cavity, and that it was simply a peculiar condition of the recti muscles. Appearances are deceptive even in diagnosticating abdominal tumors; hence the necessity of resorting to every known means for eliminating errors.

THE MEDICAL RECORD:

OUR WATER SUPPLY.

ALTHOUGH the copious autumnal rains of the past few days have quieted all present fears concerning the scarcity of drinking-water, the great possibility of a repetition of the experiences of the past summer is such as to give to the subject a more than ordinary interest. As is natural under the circumstances, the daily papers have been filled with all sorts of suggestions tending to remedy defects in the present system of supply. It is useless to refer even to the majority of the plans except in a general way as bearing upon the sanitary requirements of the day.

If we examine the present system of water-supply for New York, we have reason for congratulation that it is so well calculated, under ordinary circumstances, for meeting the wants of so large a population. It is only in view of such emergencies as we have experienced during the past few months, and in view of the constantly increasing number of consumers, that there is any reason for concern in the future. There appears to be no doubt among experts that the water-shed of the Croton is sufficient of itself to supply all possible demands which may be made upon it for years to come. So the real difficulty seems to be in the utilization of reasonable measures to increase the storage capacity of the water and to prevent its waste by the consumers. There does not seem to be any question that an increase in the number of reservoirs and the multiplication of dams will effectually overcome the first difficulty, and that an adoption of the meter system, especially in those localities where there is known to be a great waste of water, will, to a great extent at least, obviate the latter.

The proposition to tap the Hudson River near its source for the extra amount of water-supply is not to be seriously considered, except as a last resort. As a rule no towns should depend for their water supply upon navigable rivers, or any other streams liable to sewage contamination.

Although it is claimed that rivers so purify themselves by the constant changes of tide that the dangers of sewage admixture are reduced to a minimum, there is always more or less danger with the growth of towns on their banks, especially on the smaller rivers, of a pollution which may in the end be seriously detrimental to health. The great advantages of abundance in supply which a river affords is in a great degree counterbalanced by the liabilities to the dangers alluded to.

In a recent article upon the subject of river pollution, the *Lancet* says:—"It has long been patent to us that the possibility of restoring our rivers to such a condition that they would ever be fit and wholesome sources from which to supply our towns with drinking water, must be abandoned." This will doubtless, for very obvious reasons, be the experience in America, when, as in Great Britain, it may be too late for a remedy.

In respect to the Croton, however, we have all the advantages with none of the ordinary drawbacks. As such, our system is a model of its kind, and commends itself to every city or town corporation for imitation.

The time seems to have arrived when the necessities for studying the water-supply of towns is acknowledged all over the country. The well-system, which prevails in our smaller villages, is acknowledged to be inefficient and dangerous. The latter objection is more and more apparent in proportion to the increase of population and the attendant soil saturation. As the different towns enlarge, and as the growing scarcity of trees yearly increases the liability to prolonged drouths, the different corporations must secure to themselves such sources of water-supply as shall be not only abundant but pure. This has already been very satisfactorily done in several of our large cities, Philadelphia perhaps excepted, and is being done by some of the larger towns throughout the country. In the majority of these instances the sources are, as they should be, lakes, artificial or natural, in the vicinity of the towns to be supplied.

ABUSES OF MEDICAL CHARITY.

THE large number of students attending lectures in this city creates a want of clinical material for teaching which cannot fail to act unfavorably upon the young physician who depends upon his practice for his daily bread. We have already heard many complaints against the almost wilful carelessness of some of our medical teachers, in admitting improper persons to their clinics, and in prescribing for and operating upon patients who were able to pay a fee. The mere fact that a case may be interesting to the medical class is by no means a sufficient reason that it should be treated for nothing. The exercise of a little discrimination on

the part of the college professors and hospital attendants would go a great way towards correcting a shameful abuse of medical charity. It would appear, however, that many of the clinical teachers, in their efforts to fulfil an implied contract with their students, are not equal to the emergency.

THE COINCIDENCE OF TWO PERSONS HAVING THE SAME IDEAS, AND THE SAME LANGUAGE TO EXPRESS THEM.

THE *Holley Standard*, of this State, contains an article on the health of Philadelphia, which, as it is claimed as an original one by a physician who publishes it, affords an interesting example of the law of coincidences. That the writer in question should have visited Philadelphia during the Exposition is hardly remarkable; that he, being a physician, should have inquired into the sanitary condition of Philadelphia, was quite natural; but that he should have appropriated the facts gathered by us, using, in many instances, our own language to give them his authoritative expression, is a rare illustration of the manner in which two minds can run exactly in the same groove. We take no small delight in endorsing his statements, as we have special reasons for believing that they are well founded; our only regret being that they were not published in time to save us the trouble and expense of obtaining them independently. As it is, the writer has denied himself the opportunity of receiving a full acknowledgment of the benefits we would have derived from "the special pains" which he has taken "to inform himself in reference to this matter" of the health of Philadelphia. The fact of his being a little behindhand in the writing of his letter has forced him, as a matter of duty to his patrons, to publish his views in his local paper, and in this case the end may justify the means.

At first, we were inclined to entertain the idea that the doctor had read our article on the subject before he wrote his letter to the *Standard*, but we at once saw that even a vague allusion to its possibility would have seriously interfered with our purpose of illustrating a principle in the law of independent thought.

Reviews and Notices of Books.

A MANUAL OF PERCUSSION AND AUSCULTATION OF THE PHYSICAL DIAGNOSIS OF DISEASES OF THE LUNGS AND HEART, AND OF THORACIC ANEURISM. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine, and of Clinical Medicine in the Bellevue Hospital Medical College, etc. Philadelphia: Henry C. Lea. 1876.

THIS manual has been written upon a plan which the author believes to be most conducive in making it a book useful for the medical student in his daily study of the subject, and also for the practitioner who wishes a convenient manual for reference. The first object has been to throw aside needless refinements, and to treat the subject in the simplest manner possible.

The discussion of the mechanism of signs has been waived, and their destructive characters considered by an analysis especially based on variations in the intensity, pitch, and quality of sounds. Again, the author has endeavored to impress the fact, that the significance of physical signs relates to physical conditions, and that to a proper understanding of the signs, the condition must be thoroughly understood, as well as the signs of health. In other words, the student or practitioner, if he would have a correct appreciation and knowledge of physical signs as obtained by palpation, percussion, auscultation, etc., must have a thorough knowledge of the health-signs and the pathological changes, or changes in physical condition, which may give rise to changes in those normal signs.

Dr. Flint's Manual is divided into eight chapters. The first is introductory. In the second and third, percussion in health and disease is considered. The fourth and fifth chapters are consumed with auscultation in health and disease. The sixth is devoted to physical diagnosis of diseases of the respiratory system, and the physical conditions of the heart in health and disease are considered in the seventh chapter. The book is concluded with a chapter on the physical diagnosis of diseases of the heart and of thoracic aneurism.

A manual from this eminent author and teacher upon a subject to which he has given especial attention will be received with favor by the profession.

THE TREATMENT OF ANTEFLEXIONS OF THE UTERUS. By ELY VAN DE WARKER, M.D., Syracuse, N. Y. Reprint from New York Medical Journal, June, 1876. New York: D. Appleton & Company, 549 and 551 Broadway. 1876.

DR. VAN DE WARKER'S article is an argument in favor of the use of intra-uterine stem-pessaries with adjustable intra-vaginal support in the treatment of uterine displacements, or, as he calls them, "deformities." It contains wood-cuts of an instrument which he has devised for the treatment of anteversion. He does not claim that the instrument is perfect, but, with only a commendable degree of assurance, states that it has served a good purpose in the cases which are reported. There has been quite a diversity of opinion regarding the use of the intra-uterine stem instrument, and it seems that the Doctor belongs among those who regard it as safely available.

We notice one sentence in Dr. Van De Warker's paper that is worthy of quotation. It is the following: "The point in the mechanical treatment of anteversion or flexure, or, in fact, the opposite form of uterine dislocation which these cases are designed to illustrate, is that we cannot place our reliance upon any one form of instrument." If those who condemn in general the use of intra-vaginal supports for the uterus, such condemnation usually, perhaps always, being the result of ignorance of the principles which govern their adjustment, would carefully cultivate a knowledge of the fact that no single instrument is adapted to the treatment of any case, they might at least become convicted if not converted.

A MANUAL OF MIDWIFERY. By ALFRED MEADOWS, M.D. (London), F.R.C.P., Fellow of King's College, London, etc., etc. Second American Edition. Philadelphia: Lindsay & Blakiston, 1876. 8vo, pp. 484.

THIS is the second American from the third London edition. With the additions which the recent advances in the obstetric art have made necessary, the present edition is a model of its sort, giving to the student and practitioner a complete, trustworthy, and practical manual. The illustrations are quite numerous, well selected, and of more than ordinary execution.

LUMBRICOIDS PASSED THROUGH SINUS ABOVE CREST OF RIGHT ILEUM.

DR. V. P. GIBNEY:—The following case, from its triplex nature, seems sufficiently interesting to present with a history and description which possibly may seem long, but which I shall endeavor to condense as as far as practicable.

Joseph Moran, two and a half years of age, residing in Brooklyn, was brought by the mother to the out-door department of the Hospital for Ruptured and Crippled, July 19, 1876. I found almost complete palsy of the right lower extremity, voluntary power being present only in the flexors of the toes; an open sinus at the crest of right ileum, about three inches removed from the sacro ilial junctions, with a thin serous discharge therefrom; two cicatrices immediately to the right of the sacro-ilial junction, at which points, so the mother states, small spiculæ of bone have from time to time been exfoliated. The worm which is presented this evening was brought along, and the mother, with some degree of satisfaction, stated that this had protruded through the sinus only a few days before, and was seized by the child himself, who removed it with ease. During the past six months four other worms have been removed. I learned, while questioning as to the discharge of fecal matter, that for a day or two subsequent to the passage of a lumbricoid, the discharge is yellowish, and a little more fetid than usual. The general health of the little patient was good. The history, as obtained, is that in September, 1874, both lower extremities were suddenly paralyzed, the attack coming on like that of infantile paralysis. In December of the same year a lumbar abscess formed, was subsequently opened, and continued discharging up to the present time. A surgeon saw the case in May, 1875, and probed the sinus. The five intestinal worms have passed, per sinus, since that time. When the first one was passed, considerable hemorrhage occurred. The treatment adopted at the hospital was confined to the paralysis. The child has attended the dispensary regularly since July 19th, and the last note made was on September 26th, when the appetite was reported as enormous, the general health was excellent, and the discharge from the sinus slight.

Stated Meeting, October 25, 1876.

DR. CHARLES K. BRIDDON, PRESIDENT, IN THE CHAIR.

SARCOMA OF TIBIA—SCLERODERMY OF RIGHT SIDE—AMPUTATION OF LEG.

DR. JOHN W. HOWE presented a specimen of sarcoma of tibia, scleroderma of right side, with the following history:—

Maggie Sealy, aged nine, was admitted to St. Francis' Hospital in April, 1876. In December, 1873, she fell from the bed and bruised the inner side of the right knee. It soon after became swollen and painful; the integument over the injured part was roughened and harder than natural. In about four weeks the roughening and induration extended as high as the groin; then it travelled downwards along the inside of the leg to the ankle. Some pigmentation of a brownish color accompanied the induration, but was not confined to the diseased parts. At the end of four months from the accident the sclerosis had extended up the small of the back as high as the scapula. There was a small spot on the chin, and over the right side of the scalp there was considerable pigmentation. The affected integument had the appearance of cicatricial tissue in many parts. It was colder than the healthy skin.

No hereditary taint could be found on examination in the hospital. The patient was found to be exceedingly emaciated and weak; the *sclerionxis* was about the same as described above. Over the inner side of the leg, extending upwards almost five inches from the inner malleolus, there was a large ulcer covered with flabby granulations, bathed in thin fetid pus. She complained of constant pain of the sore. The thigh was flexed on the body. The flexor tendons were exceedingly rigid, and seemed to be incorporated in the indurated integument. The ham-string muscles were in a similar condition.

Cod-liver oil, quinine, and iron were ordered, and a solution of carbolic acid applied to the ulcerated surface. Rapid improvement in her general health took place. She gained flesh and strength, and was able to go about the ward with ease. This improvement continued up to August last, when an enlargement of the leg corresponding to the ulcer was noticed. Both bone and soft parts seemed to be involved. A large fungous mass grew rapidly out from the seat of the ulcer. It had an extremely fetid odor and was covered with serous pus. There was constant and intense pain shooting up and down the leg, as well as over the tumor.

As the child was running down rapidly, it was decided to amputate. The operation was performed on Sept. 29th, through the middle of third of the femur. I made lateral skin flaps; the inner one from the indurated integument, and the external one from healthy tissue. The flaps were brought together in the ordinary way, but in a day or two it was found necessary to take out the sutures on account of the sloughing of a small portion of the upper angle of both flaps. Since the operation the little patient has experienced great relief; is able to be up and dressed every day; the stump is also doing well; but owing to the profuse growth of granulations, perfect union has not yet been attained.

When the soft parts were cut away from the bones of the amputated leg, it was found that at the base of the fungous mass there was a corresponding enlargement of the tibia, about four inches in length, irregular in shape and very porous. The os calcis-astragalus and some of the metatarsal bones were soft, carious, and contained pus.

The microscopical examinations of the growth on the tibia do not seem to agree. Dr. Edel found nothing but new bone formation in a state of atrophy, with a few marrow cells. Drs. Delafield and Stillmann found large masses of spindle-shaped and round nucleated cells, and pronounced it a sarcoma of the most malignant type. Dr. Heitzmann, judging merely from the gross appearances of the specimen, agreed with Dr. Edel, but on hearing the history of the case changed his mind.

DR. GIBNEY remarked that he had a case similar to the one related, the particulars of which he had already presented to the Society. The patient was eight years of age, and had a patch upon the chin, to the left of the symphysis, with a deep cicatrix in its centre as if made by some sharp instrument. The mother stated that the same condition of integument

existed over the left nates, the posterior surface of the calf, and the middle of the thigh. This condition of things had then existed for three years without any special change, and the child was merely brought to Dr. G. to be treated for lameness. The left thigh was one inch smaller in circumference than the right.

THE DEVELOPMENT OF SARCOMATOUS TUMORS.

Dr. C. Heitzmann presented microscopic specimens of sarcoma tumors grown in the subcutaneous tissue and in glandular organs, such as the liver, the submaxillary salivary gland, in order to demonstrate the changes in the epithelial elements produced by the growth of sarcoma. These changes had been studied in his laboratory by Dr. Rudolph Tauszky, of this city, and described in the Transactions of the Imperial Academy of Sciences of Vienna, vol. lxxiii., 1876. The changes generally are of two kinds; first, those which can be considered as being simply inflammatory ones; and secondly, those which lead to the production of sarcoma-elements from epithelial bodies. Changes of the first kind were to be observed in the rete mucosum of the skin, covering a sarcomatous growth, without having however undergone any ulceration; here the melting of the cement substance takes place, and new-growth of indifferent elements arises through the increase of the living matter—the granules within the protoplasm as well as in the spaces belonging to former cement-substance, from the uniting threads, the so-called thorns of Max Schultze. This was one proof more that these threads really were formations of living matter. Changes of the second order, the transition of epithelium into the sarcomatous tissue, could be demonstrated in glandular organs. After the solution of the cement-substance endogenous new-growth of living matter took place, this giving rise to new elements, which after having undergone a partial change into basis-substance, were perfectly identical with the elements of the original tumor. Thus the protoplasm of genuine epithelial formations directly changed into that of the sarcoma, and only scanty remnants of the epithelium might be met with in glands, for instance in the testicle, if the seat of sarcoma, in which kind of tumors, as universally acknowledged, no formation of epithelium took place.

EXSECTION OF HIP.

Dr. Briddon presented a specimen of exsection of hip, with the following history prepared for him by Dr. A. F. Buhler:

William Nienberger, æt. 2, New York. Admitted Oct. 5th. Service of Dr. Briddon.

History.—Father died of consumption; history on mother's side good. Up to the age of eight months the child, according to the mother's statement, was perfectly healthy. At that time the submaxillary glands on the right side began to enlarge, became inflamed, and were attended by the formation of abscesses. Ten months ago, when the present disease made its appearance, the child, accepting the mother's history, was enjoying good health. There is no history of an injury being sustained. The first symptom to attract the attention of the mother was, that one morning on getting out of bed the child began to limp. This limp lasted for an hour or two, and then disappeared. The next morning it again returned. The mother also noticed that the child in walking would rest his diseased limb on the tip of his toes. About three months ago the child became very restless and feverish at night. He would cry during a great portion of the day, and point to his hip with an expression of pain. At this time an abscess formed on the outer portion of the thigh, at the junction of the upper and middle third.

On examining the patient, it is found that the nates are broadened and flattened. The gluteo-femoral crease on the affected side is lower and less distinct than on the other side. The leg is flexed on the thigh everted and abducted. There is an apparent shortening, but on measuring both limbs from the anterior superior spinous process to the inner malleolus no difference in the length of the two can be detected. On making pressure over the great trochanter, and thus bringing the articular surfaces of the bones in contact, or by rotating the limb, an expression of pain is excited on the child's countenance. A sinus is also found at the junction of the middle with the upper third of the thigh on the outer surface.

October 16th.—Operation by Dr. Briddon.—The sinus situated on the outside of the thigh was opened to its termination; it communicated with the anterior surface of the articulation, the capsular ligament of which appeared to be entirely destroyed, and this disposition of the articular extremity of the sinus made the separation of the soft parts somewhat tedious, it being necessary to work from before backwards instead of in the opposite direction. In attempting to turn out the head of the bone a separation of the superior epiphysis took place, leaving the head "in situ;" a chain-saw was carried round the exposed end of the diaphysis and about three-quarters of an inch removed; the head was then removed without further difficulty.

The acetabulum was nearly filled with granulation tissue, but there was a denuded point on the posterior border of the ischium that was scraped with Simon's spoon. On inspecting the parts removed it was at first thought that a separation at the epiphysis had occurred before the operation; but a more careful examination determined that such lesion had been caused in the effort to dislodge the head.

It was difficult to decide from appearances whether the disease had begun on the surface of the articular head, or whether the joint had become involved secondarily from disease spreading progressively from the cancellous structure; the under surface of the neck was hollowed out into a cavity that communicated with the joint. The head of the bone was divested of cartilage, save at its periphery. After the very trifling hemorrhage had ceased, the patient was placed upon a Sayre's cuirass, and the wound resulting from the operation was then painted over with balsam of Peru, and its cavity filled with oakum. The child readily recovered from the shock of operation, but passed a rather restless night. Patient's temp. in the morning following the operation, 101¾°. Evening temperature, 100°.

October 18th.—The dressings were to-day removed, and on inspecting the wound it is found to be in an excellent condition, discharging pus pretty freely. The dressings were again renewed, with orders to have them changed daily.

October 24th.—Healthy granulations now fill up the lower portion of the wound. Patient's temperature has never exceeded 101¾°, his appetite is good, his sleep is undisturbed, and his general condition excellent.

A UNIQUE CHEST WOUND FROM EXPLOSION OF A CARTRIDGE—AN INTERESTING QUESTION CONCERNING OPERATIVE INTERFERENCE FOR THE REMOVAL OF THE FOREIGN BODY.

Dr. H. B. Sands presented the anterior portion of the right lung removed from the body of the late Dr.

Thebaud, whose death was caused by the premature explosion of a cartridge which at the time of the accident he was engaged in filling. Although originally of a robust constitution, Dr. Thebaud had suffered from repeated attacks of pleurisy, of precordial pain, and also of dyspnœa, which latter was suspected by some of his medical friends to be due to disease of the heart, aorta, or both. He had been examined by Drs. Leaming, Loomis, and Metcalfe, all of whom had detected a systolic murmur at the base of the heart, and one of whom considered it organic in character. Immediately before the accident the patient was in better health than usual.

The accident occurred on the 12th of October, about 9 P.M., and while the patient, deceased, was seated at his dining-table, in the second story. Immediately after its occurrence the doctor rose and made a desperate effort to reach his bedroom in the story above, and sank exhausted across the foot of his bed, bleeding from a wound in his chest. The little finger of his right hand was also wounded, but the wound was comparatively of little moment. Dr. Sands was summoned immediately afterwards, and arrived at the house at 9.30 P.M. He saw the patient in consultation with several gentlemen who were present—Drs. Briddon, Stimson, Reynolds, and R. W. Taylor. From these gentlemen he learned that Dr. Thebaud was rallying from a profound and dangerous shock; in fact, at that time he was nearly pulseless, and was slightly delirious. On examination, an oblique incised wound of the chest was discovered, a little more than an inch in length, running from above downwards, and from without inwards, directly over the fourth intercostal space, and very near the right side of the sternum itself. From this wound there was pretty active hemorrhage, which evidently came from the interior of the chest. As soon as the patient rallied sufficiently to admit of an exploration of the wound, Dr. Sands introduced the end of the left little finger into it. After passing it in to the extent of an inch and a half, directly backwards, its progress was arrested by soft tissue, and any further attempt at examination, in view of the proximity of vital organs, was for the time abandoned. A subsequent examination, made directly afterwards, the bleeding continuing, revealed a portion of pasteboard cartridge, which was removed. Circumstances admitting, a careful visual examination was made of the wound with a view of finding the source of hemorrhage, which was evidently venous and quite free. The attempt was unsuccessful, and ice compresses, lightly applied, at once controlled the bleeding. After this the patient was placed square around in bed, covered up warm, and left.

On the morning of the following day the patient spat blood, which confirmed a previous suspicion that the lung had been wounded. He had passed a bad night, and expressed his conviction that he was suffering from internal hemorrhage. Auscultation and percussion were practised, as far as practicable, but gave negative results. The heart-beat was feeble, and the old murmur was easily recognized. On the afternoon of this day (Friday) the coat was removed, the patient propped in bed, when auscultation was more satisfactorily performed. It was then that the presence of abundant crepitant râles was discovered. These were thought by Dr. Sands to be due to blood from the wounded lung. Opium was administered for the first time on this day, and continued during his illness, when restlessness, dyspnœa, and pain required it.

On Saturday (third day) he again expectorated blood, and there were signs of commencing pneumonia. No perceptible change on Sunday, except incipient delirium, which continued more or less until death, which occurred by syncope.

On Tuesday (17th) precordial pain, which commenced the day previous, increased, and respiration became more labored. At this time he had a well marked exacerbation of fever, and quinine was administered.

Wednesday (18th) he began to fail markedly, and in the evening he approached absolute collapse. The latter was prevented by the hypodermic injection of brandy and caffeine. From this time he continued gradually to fail, until 3.50 A.M. of Monday, the 20th, when he died.

During his illness his pulse ranged from 90 to 120; his respiration was subject to great variations, ranging from 18 to 55 per minute. The range of temperature on the evening of the accident was 96° F., then it arose to 99° and 101°, remaining thus until the last day, when it sank to 97°.

The autopsy was made by Dr. Finnell, during which the pericardium was accidentally opened by the deputy coroner. On raising the sternum a square piece of the brass cartridge cylinder (1⅛ inches) was found firmly imbedded in the anterior portion of the lung. The right margin of this piece of brass was concealed from view, while the left margin presented a sharp angular edge, which penetrated the lung, made a small perforation into the pericardium, and lay in direct contact with the left ventricle of the heart.

There was universal pericarditis, the diagnosis of which was made during life by Drs. Stimson and Reynolds. Between the parietal effusion and the heart was a quantity of blood, estimated by Dr. Finnell at a pint. The blood did not come from any large vessel, and Dr. Sands was of the opinion that the greater portion was from the lacerated lung-tissue, and had entered through the wound in the pericardium. The right auricle contained a post-mortem clot. No lesions of the aortic valves were discovered, proving the correctness of Dr. Leaming's diagnosis.

The lungs were universally adherent on both sides. The lungs were contracted and found the seat of organic disease.

In conclusion, Dr. Sands discussed the propriety of more thorough exploration of the chest, and the advisability of any attempt to remove the foreign body. He maintained that in Dr. Thebaud's case the circumstances were such as absolutely to forbid a more thorough exploration, and also any attempt to extract the foreign body. Aside from the condition of extreme shock in which the patient was during the greater part of the time subsequent to the injury, the existence of organic disease of the lung, and the dangerous proximity of the heart, were of themselves sufficient reasons for the unjustifiableness of operative interference.

Dr. Finnell next presented the lungs of the deceased. He stated that they were in the condition of fibroid degeneration, the result of chronic pneumonia; that they were universally adherent; and that, although the missile was imbedded in the pulmonary tissue for eight days, no inflammatory changes were noted in its neighborhood. He gave it as his opinion that the hemorrhage in the pericardium was due to the wounding of the vessels on the surface of the heart by the sharp projection of brass against it. He thought that a fresh scratch was made by these means almost at every pulsation. This was, to his mind, also an explanation for the universal pericarditis. During an unfortunate slip of the cartilage knife of the deputy coroner, the pericardium was opened, and as near as could be estimated by sponging up the

blood which flowed from that cavity and squeezing it afterwards in a bowl, its quantity was estimated to be a pint.

Dr. Sands did not think that the quantity of blood in the pericardium was so large; and further, he was of the opinion that the pulmonary tissue around the wound was considerably altered, showing inflammatory changes.

Dr. Leaming said: Dr. Thebaud called at my office in company with Dr. F. N. Otis, some time last spring, and I made an examination of his chest.

There was very little expansion; dry râles over both lungs, varying in size and sonority. In ordinary breathing they were absent under lower angle of scapula, but a slight cough, when the ear was pressed against the chest-wall at this point, would cause to be heard a quick succession of fine râles like crepitus. Beyond the râles true respiratory murmurs could be heard, except at summit of lungs.

There was a systolic murmur at the base of the heart, at the apex, and in the chest-wall over the left side. It was an audible murmur, caused by unequal tension of the chordæ tendineæ, due to slight dilatation of the right cavities of the heart from obstruction of pulmonic circulation by firm interpleural adhesions. I was told that aneurism of the arch of the aorta, stenosis of the mitral valve, and obstruction at the aortic orifice had been diagnosticated. I listened again, but did not find them.

A few weeks afterwards, Dr. Thebaud again called on me in company with Dr. Reynolds. I made another careful examination, which confirmed me in my first diagnosis.

In regard to the soft moist râles heard over the right lung the day before his death, and which had been noticed several days, we have now positive proof of their interpleural origin. *They could not have been formed in the bronchii during the last day, because the lung was filled with exudative matter, and no air could enter.* Air-sacs and bronchiæ were full. But the effort to breathe caused the lung to move bodily in the thorax, stretching the adhesions moistened by fresh exudation, and characteristic râles resulted.

The wound evidently was mortal from the first, and the autopsy justifies Dr. Sands' conservative surgery. If the foreign body could have been found, its removal would have further lacerated the lung, renewing and increasing the hemorrhage, and would have left a ragged opening in the pericardium, which filling with blood would have caused speedy death.

Dr. James R. Wood stated that the wound of Dr. Thebaud was a fatal one from the beginning, and that Dr. Sands was right in stating that no surgeon would have been willing to explore the thorax of the patient with a view to ascertain where the foreign body was. Again, even if the missile could have been reached, the patient's condition during his whole sickness was of itself a sufficient reason to let him alone.

Dr. Briddon thought that the quantity of blood in the pericardium was very much overestimated. He saw only three or four clots, the fluid being evidently the product of inflammation, mixed with blood. In regard to the condition of the patient, the first time he saw him he remarked that, to his mind, it was so critical that he did not expect him to live until morning.

Dr. Wood did not see how the patient could have lived so long with a pint of blood in his pericardium.

Dr. Stimson asked if there was such a quantity of blood in the sac, how it was that pericarditis could be diagnosticated.

Dr. Leaming said that such a diagnosis would have been impossible under such circumstances; and, further, that death would have been sudden.

Dr. Van Geison wished to reconcile the conflicting opinions in regard to the quantity of blood in the pericardium by suggesting that its effusion might have been gradual, and that the critical time was reached when the pericardium was full.

Dr. Robinson gave some of the reasons why the effusion in the pericardium, allowing it to be serous, might not have been in whole, or at least in part, dependent upon the presence of heart-clot.

Dr. Stimson, who had been in constant attendance upon the patient, fully endorsed Dr. Sands' views in regard to the inexpediency of operation. Indeed, the patient was, in his opinion, doomed from the beginning.

Dr. A. C. Post fully corroborated this opinion, maintaining that any operative interference, under the circumstances, would have been positively unwarrantable.

Dr. J. W. Howe asked, in case the patient had not been so prostrated, whether an attempt to remove the foreign body would not have been admissible.

Dr. Briddon thought that dangerous hemorrhage would have been the result. The edge of the piece of brass was so near the internal mammary artery that it was a miracle that it escaped at all.

Dr. Post remarked that in case the patient was in condition, and even in case the cavity of his chest could be seen as through a glass, any attempt to remove the missile would have been inadmissible.

Dr. Reynolds stated that so profound was the shock during the night of the accident, that it was not until the following morning that the temperature could be marked at the lowest register—96½° F.

Dr. Heitzmann stated that, had this case occurred in Vienna, the treatment would have been precisely the same.

Dr. Allin then presented a specimen for a candidate, after which the Society went into Executive Session.

Correspondence.

RADICAL CURE OF EMPYEMA.

To the Editor of The Medical Record.

Dear Sir:—In your impression of October 14, 1876, No. 310, p. 669, I observe an article entitled "Radical Cure of Empyema," extracted from the "*Berliner klin. Wochenschrift.*" Three "desperate cases" of empyema are therein detailed, which were relieved by resection of the rib. In each case incisions sufficient to permit free drainage were made, but the wounds would gradually close, and all the symptoms become aggravated. Upon the removal of a portion of the rib, in each case, improvement was promptly introduced, resulting in each instance in permanent recovery.

While observing with pleasure that the attention of your readers is being directed to this excellent procedure, it is the purpose of this communication to call attention to the fact that this method has long been known and practised in the United States, instead of being an entirely new procedure, as seems indicated by the article alluded to from the columns of your German contemporary.

In the autumn of 1871 I first saw this operation performed by the late Dr. Warren Stone, of New Orleans,

at his clinic in the Charity Hospital of that city. He performed the operation several times during the following winter, the result being quite favorable in each instance. I saw the same operation performed subsequently, in the same institution, by Dr. T. G. Richardson, the successor of Dr. Stone to the chair of surgery in the University of Louisiana. In these instances the point selected for the operation was about an inch posterior to the axillary line. After exposing the seventh or eighth rib at this point, the trephine was applied and a section of the bone removed.

It is claimed for this operation, as stated by the article in your columns, that in addition to furnishing a free outlet for the pus, the size of the cavity is reduced by the approximation of the divided ends of the resected rib.

Experience with this method of treatment, in so far as has been recorded, would certainly justify a more frequent resort on the part of surgeons to resection of the rib in obstinate and severe cases of empyema.

I am sir, very respectfully,

L. S. McMURTRY.

DANVILLE, KY., October 17, 1876.

Medical Items and News.

THE LATE DR. J. S. THEBAUD.—At a meeting of the New York Pathological Society, held Nov. 8, the following resolutions were adopted:

Whereas, It has pleased God to remove from the sphere of his earthly labors our late friend and associate, Dr. J. S. Thebaud; therefore,

Resolved, that by his death we are called upon to mourn the loss of one deservedly eminent in our profession, who has been suddenly cut down in the midst of a career of prosperity and usefulness.

Resolved, that we will cherish the memory of our departed friend, whose high moral and social character won the affection of all who knew him, and whose professional ability and attainments entitled him to universal respect and admiration.

Resolved, that we extend to the family of the deceased our cordial sympathy with them in their bereavement.

Resolved, that these resolutions be published in the medical journals of this city.

H. B. SANDS,
DANIEL M. STIMSON,
J. B. REYNOLDS,
Committee.

THE TREATMENT OF CHANCROIDS BY ACTUAL CAUTERY.—Dr. Henry G. Piffard, of this city, advocates the application of actual cautery for the local treatment of chancroids, as being more thorough and effectual than the usual means employed. The platinum wire is bent upon itself, heated to whiteness, and after being applied, a few drops of carron oil are dropped upon the surface of the sore (*Archiv. of Clin. Surgery*).

TO DESTROY LICE.—The *Med. and Surg. Reporter*, Philadelphia, recommends the following wash to be used once a day for three or four days:

℞. Hydrarg chloridi corrosivi	gr. iv.
Alcoholis	ʒ i.
Aquæ coloniensis	ʒ ij.
M.	

GASTROSTOMY.—Professor Verneuil, of Paris, has just done this operation successfully in a case of œsophageal stricture of traumatic origin. Two months after the operation the patient was up and about, attending to the lighter duties about the hospital (*vid.* page 764).

CONCERNING THE SO-CALLED CENTENNIAL FEVER.—Dr. W. W. R., of Brooklyn, N. Y., writes: "Much has been said and written in regard to the sickness that seems to have very generally attended a visit to the Centennial Exhibition, and, as far as I have seen, the cause has been mainly imputed to a bad sanitary condition of the city, and the grounds of the Exhibition. Whatever that condition may have been and still is (and I have thought the defence made by Dr. Pepper on behalf of the city altogether tenable), I am convinced that the cause of the characteristic fever mainly lies in the presence of *fomites*—certain articles on exhibition, which have been brought from some of the worst plague spots of the earth, of Egypt, Africa, India, Asia, and South America. These have been brought in closed boxes, opened and placed on exhibition for months in poorly-ventilated buildings, chiefly, however, the densely-crammed Main Building. Is herein not a sufficient origin for all the obstinate, typhoid states of the system we have witnessed among patients who have visited the Exhibition?

"It has been argued, however, that there have been more cases of typhoid in Philadelphia this season than for a long time before. And why not? The visits of her citizens to the infected buildings, and their equal susceptibility with other persons, reasonably explain such increase.

"The cases of simple diarrhœa, so very common, can readily be imputed to the drinking of water to which sufferers were not accustomed; new, sweet cider made on the grounds; sloppy, artificial beverages, and eating fancy cakes and the like.

"In view of the foregoing facts, as I believe them to be, I venture to predict that we shall find in the future, more or less, types or grades of fever not heretofore familiar to us in this country—one of the consequences of the great Centennial International Exposition."

Upon the same subject Dr. Julius Fehr, of Hoboken, N. J., sends us the following:

"It is certainly surprising that no one in Philadelphia seems to think of the dangerous proximity of Laurel Hill Cemetery to the Schuylkill. The surface-waters and surface-springs, by the telluric formations of this extensive cemetery, must evidently gravitate to the Schuylkill and produce a contamination of the water, far worse, in fact, than any other. This may lead to explain why there was not 'that centennial fever' during our hot and dry summer, and why it appeared only in fall, when the rainy weather set in, and 'Laurel Hill' was, in fact, after that long interval, anew 'extracted by percolation.'"

DR. J. S. BILLINGS, Assistant-Surgeon U. S. A., and Librarian of the National Medical Library at Washington, is in London, charged with a double mission of securing a collection of missing pamphlets for the library, and of collecting information regarding hospital construction for the benefit of the Johns' Hopkins Hospital, of Baltimore. From accounts in the English journals he has received a flattering welcome.

BARON LIEBIG is to have a statue. More than the necessary amount is subscribed.

SAINT BARTHOLOMEW'S HOSPITAL.—A large part of the school buildings of Saint Bartholomew's will be entirely rebuilt on an extensive scale next summer.

BRITISH ARMY MEDICAL DEPARTMENT.—The Army Medical Service in Great Britain is so much in want of medical officers that civil practitioners have to be employed.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending November 18, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Nov. 11.....	0	18	53	4	12	47	5
" 18	0	12	46	3	3	60	0

The Thames Mud-Butter.—The latest London industry is the collection of oleaginous deposits in the mud of the Thames. It is quite profitable, the mud gatherers making three shillings and sixpence a day. Small globes made of cork and lined with hair are planted in the mud at low tide and the fatty substances in the water adhere to them. This miscellaneous grease is manufactured into fresh butter for the London market, at least so say the London papers.

Weekly Bulletin of Medical Societies.—In the course of the next fortnight we shall endeavor to commence our weekly bulletin of Medical Societies. The Secretaries of the various organizations will please send their notices at *the earliest possible moment*, with the titles of papers to be read, to the Editor, 38 East Thirty-second street, N. Y.

Private Medical Schools.—Two private Medical Schools have been started in London.

The Practice of Medicine in Texas.—A new State law of Texas provides that hereafter no one shall practise medicine within the said State without being qualified to do so by a license from a board of examiners from one or other of the judicial districts. The boards are to meet semi-annually at some central point. The fee of the board is twenty-five dollars for each applicant.

Dr. Grainger Stewart, well known in this country by his admirable work on Diseases of the Kidneys, has been appointed Professor of Medicine at the University of Edinburgh.

Sir William Fergusson has so far recovered as to be able to resume his private practice in London.

Desault.—A bust of Desault was publicly unveiled on October 15th, at Lure (Haute Saône), his native city.

Medical Women in Ireland.—Six women were recently refused admission to the Queen's College, Galway, by the Council of that Institution.

Cholera is still prevalent in Peshawur.

The Discovery of the Circulation of the Blood.—A bust of Andrea Cesalpino, as the discoverer of the circulation of the blood, was unveiled October 30th, in the library of the University of Rome. His claims were advocated by Prof. Scalzi, who delivered an address on the occasion.

Cause of Decay of the Teeth.—Dr. L. B. Palmer, of New York, has been led to conclude, from a series of experiments, that the decay of the teeth is not, as is generally supposed, due to acids, but to alkalies. With alkalies he reproduced decay of the teeth as it is seen in the mouth, but was unable to do so by acids. With the assistance of an electric current, acids simply acted on and destroyed the whole of the enamel.—*Amer. Jour. of Dental Science.*

Remedy for Dandruff.—A French physician (Apoth. Ztg.), claims to cure this troublesome affection by applying a solution of chloral hydrate, containing five per cent. of the latter, by means of a sponge, and repeating it every morning. If the hair has fallen out in consequence of the dandruff, it is claimed that the said hair will reappear in a month.

The Statue to the late Sir James Simpson, Bart., M. D.—Concerning this statue the *British Medical Journal*, Oct. 28th, says:

"The bronze statue of the late Sir James Simpson is now in the artist's hands, and stands ready to be removed to the site fixed upon for it, viz., in the East Princes Street Gardens, as soon as the pedestal on which it is to stand shall be erected. The casting produced by Messrs. Masefield, of Chelsea, turns out to be one of unusual excellence. The statue represents the subject in the sitting posture, and is eight feet in height, corresponding to a standing height of twelve feet; the pedestal is to be ten or eleven feet high. Sir James is represented in academic robes, sitting erect with the face turned towards the left shoulder, in the attitude of a man earnestly enforcing his convictions; while the right hand supports one side of a large book which rests on the knees, the left is engaged in turning over the leaves. In modelling the massive head, Mr. Brodie had the busts executed by himself from the life, and he has been very successful in reproducing both the features and the tenacious expression of the original. This part of the casting is peculiarly effective in the sharpness and precision with which it gives every touch of the graving tool; and the same may be said of the hand, in which the sculptor has vividly realized another characteristic feature."

A Pessary Imbedded in the Vagina for Thirty Years.—At the Abernethian Society of St. Bartholomew's Hospital, on Thursday, October 19th, Dr. Maberley showed an old-fashioned pessary, flat and circular, about three inches in diameter and with a hole in the centre. It was extracted from the vagina of a woman, aged forty-five. The history showed that it must have lain there for nearly thirty years unknown to herself. It was inserted by a distinguished obstetric physician, and the girl (as she then was) appears to have misunderstood what was said at the time to her mother respecting it. The pessary has, of late years, caused very unpleasant symptoms, which remained unexplained till it was detected and removed by Dr. Godson.—*Students' Journal and Hospital Gazette*, Nov. 4.

The New York Aquarium Journal. Edited by W. S. Ward. Nos. 1, 2, 3.—This is a semi-monthly illustrated journal, devoted to the interests of the new Aquarium, and is mainly made up of interesting facts and fancies concerning the peculiarities and habits of the various members of the finny tribe on exhibition at the institution. Some of the articles are selected, while others are written specially for the *Journal* by gentlemen well versed in ichthyological lore. One column in each issue is devoted to the entertainment of the young folks. The really interesting matter which the *Journal* contains, and the low subscription price (fifty cents a year), should make it a welcome addition to the family circle. In the third number it is stated that the library of the Aquarium, a large and well-furnished room, is at the service of any organized scientific body that may desire to occupy it for special or regular meetings, *free of charge*. Applications to be addressed to Mr. W. S. Ward, at the Aquarium, cor. of Broadway and Thirty-fifth Street. This is a liberal offer which some of our medical societies would do well to consider.

Original Communications.

COLD BATHS IN THE TREATMENT OF TYPHOID FEVER.

ILLUSTRATED BY TWO SEVERE AND SUCCESSFUL CASES.—REMARKS ON THE PRINCIPLES INVOLVED.

By LOUIS GIGNOUX, M.D. (Univ. Paris),
PHYSICIAN TO THE HÔTEL-DIEU, LYONS, FRANCE.

Hattie G., eighteen years old, was attacked with typhoid fever the first part of December last. Upon the eighth the disease was clearly defined; after the initiatory headache, feebleness, diarrhœa, distended abdomen, rose spots, intense fever, 41° Centigrade (105.80° F.), slight morning remission 40.8° C. (104.44° F.). At this time a bronchitis was observed with mucous rales, a few dull points at the base of the lungs, with a little temporary bronchial respiration.

About the twelfth day there occurred a large intestinal hemorrhage, which was repeated the thirteenth and the fourteenth day. I was called in upon the fifteenth day, and found her in the following condition: Dorsal decubitus, very marked typhic appearance, yellow congested conjunctiva, dull expression of countenance, intelligence obscure, still recognizing me, sub-delirium the moment the attention is not held; abdomen very much distended, covered with red spots, stools involuntary, blackish, formed of blood which had laid in the intestines; tongue parched, black, the patient refusing to take scarcely any food, or even liquids, and vomiting if she is forced to swallow any. Numerous sub-crepitant rales, disseminated over the lung, respiration very obscure in certain points, in other points a little souffle. Slight dullness at the base of both lungs, short, frequent respiration, 46 a minute. Since the hemorrhages the pulse has been very small, intermittent, 140 to 145 a minute, heart-sounds very feeble, beginning of an eschar over the coccyx. The heat is intense, the thermometer left in the rectum for five minutes registers 41.4° C. (106.52° F.). The patient is attended by two distinguished physicians, Dr. Lambron, *médecin-inspecteur des eaux de Luchon*, and Dr. Grandvilliers, both *ancien internes* of the hospitals of Paris.

In the presence of so serious a condition, and so elevated a temperature, I did not hesitate to advise the cold bath. The physicians did not immediately accept this proposition; they objected on account of the chest symptoms, which they rightly regarded as very serious, and which in my opinion was precisely the reason why the employment of the baths was urgent. The physicians proposed a blister over the whole of the back, which I did not agree to; I accepted only dry cups over the chest and the use of very cold affusions over the whole body. It was, however, agreed that if these lotions did not diminish the temperature in a marked degree, cold baths should be employed, for it was impossible to admit that life could be prolonged more than two or three days with a temperature exceeding 41° C. (105.80° F.). The cold affusions were made with great care, a quarter of an hour at a time, without producing any result, the thermometer remaining stationary between 41.2° and 41.4° C. (106.16° and 106.52 F.). After having thus lost twenty-four hours, during which time the feebleness and the difficulty of respiration continued to increase, it was decided to give the baths. I put her then in a bath at 20 C. (68 F.), where I left her for fifteen minutes. She was almost insensible to the impression of cold, not shivering at all. After the bath she was put back into bed, hardly wiped off, and a light covering thrown over her. A quarter of an hour after the bath the rectal temperature was 40 C. (104° F.). I was pleased to see the bath had produced its effect. I made her swallow three or four spoonfuls of soup, stopping when efforts at vomiting manifested themselves. Before the bath I had caused her to take a spoonful of sherry. The general condition unchanged. The bowels were kept constantly covered with cold compresses, renewed every five minutes. Three hours after the bath, rectal temperature 41.1 C. (105.98 F.). Another bath, just like the preceding one; wine before, soup after. Upon going into the bath and upon leaving it, the head was sprinkled with water at 15° C. (59° F.). I was very careful to keep her in the water up to her neck, an important precaution with all, and especially with her, on account of the thoracic complication. Upon leaving the bath, rectal temperature 40 C. (104° F.); general condition unchanged. Three hours after, temperature 41° C. (105.80 F.). Another bath; half an hour after, 40.1 C. (104.18 F.); the baths are well borne; the adynamic condition is still too profound to permit the patient to be sensible to cold; she does not complain, nor has she any chill; she appears to have a tendency to sleep, so that we never fail to give before the bath one or two spoonfuls of Madeira wine or of port, and during the bath the legs, the thighs, and the arms of the patient are kneaded with the hand. Some involuntary black stools; bladder paralyzed and distended; urine red, withdrawn by the catheter. Three hours after, temperature 40 C. only (104° F.). Another bath exactly like the preceding one. After the bath, 39.2 C. (102.56 F.). This bath has been accompanied with a little shivering, which continued after the patient was placed in bed. After the bath, there was for the first time a little cough, the bronchial sensibility being aroused. Up to this time the patient had never coughed, notwithstanding the great pulmonary engorgement. Three hours after, temperature 40 C. (104° F.). Bath; after the bath, 39° C. (102.20° F.); cough more marked, slight expectoration. The patient always takes before each bath a large spoonful of wine; after each bath three or four spoonfuls of soup; unfortunately, no more could be given.

The seventeenth day: She had taken up to that time eight baths in twenty-four hours; the temperature no longer rose above 40° C. (104° F.), remaining about two hours and a half at 39° C. (102.20° F.) between the baths, increasing at the end of that time, as could be perceived by the redness of the cheeks, the agitation, the delirium which returned; for after the bath she began to have a little tranquil sleep. The physicians, perceiving that the general condition was about as serious as before, proposed to stop the baths. They were especially impressed with the smallness of the pulse, which was very feeble, intermittent, and always 45 per minute. I assured them that in the treatment by cold baths it was unnecessary to pay much attention to the state of the pulse, which was always small, contracted, and very bad; that these intermittences were observed before the baths, and was due to a fatty degeneration of the heart produced by a long continued elevated temperature, and also by the previous intestinal hemorrhages. I also caused them to observe that auscultation did not reveal any greater disorder in the lungs, and that the respiration had diminished to 36 per minute. I was permitted to continue.

Eighteenth day: Condition about the same; before the bath, 40 C. (104° F.); after, 39.2°, 39.1°, 38.9° C.

(102.56°, 102.38°, 102.02° F.). Cough more marked; a little more expectoration; alimentation perhaps a little stronger, four or five spoonfuls each time; calm sleep between the baths. Respiration diminished to 34, and auscultation reveals to the physicians a notable amelioration; urine less red (since there is less fever), more abundant, always withdrawn by the catheter.

Nineteenth and twentieth days: Same condition, same treatment. Amelioration more marked, except by the pulse, which remains 150, very feeble, irregular; but the intelligence is less troubled, she is delirious only at night; complains of the bath and desires to be taken out, chills sooner and for a longer time. There is still a little cough and expectoration, nothing more perceived upon auscultation. Alimentation increased a little. Urine clearer and more abundant. Eschar upon the sacrum does not increase; the stools are soft, dry, no longer black; respiration has fallen to 30.

For eight days the same treatment was continued without any modification. A bath at 20° C. (68° F.) for fifteen minutes, an aspersion always before the bath and one after, two spoonfuls of wine before the bath (which makes about two ounces a day), after the bath a coffee cup of semi-liquid food, soup, coffee with milk, tea, chocolate with milk or water, arrow-root, etc.; respiration 26–28 per minute.

At this time, the twenty-eighth day, the temperature before the bath was found to be only 39.5° C., 39.3° C. (103.10° F., 102.74° F.). The bath then was given only for twelve to thirteen minutes, always at 20° C. (68° F.). It produced its usual effect—a diminution of a degree. They were continued.

The following days, three hours after the bath, temperature 38.5° C. (101.30° F.). Bath omitted and soup and wine given, waiting three hours, then the temperature rising to 39° C. (102.20° F.), the bath at 20° C. (68° F.) given for ten minutes.

Finally, she took only two or three baths a day, when the temperature showed 38.5° C. (101.30° F.), and after a few days at 30° C. (86° F.), the temperature not rising above 38.5° C. (101.30° F.). The baths were stopped, convalescence began. The appetite was insatiable, and it was necessary to restrain it. Chicken and other food was given only after ceasing to give the baths. The stools were natural, and for some days had a form; urine limpid, eschar upon the sacrum not yet cicatrized, but looking well. The pulse was still feeble, frequent, 140, irregular, and this condition continued several days, necessitating the administration of wine in larger doses. The patient remembers nothing, not even her baths, unless the last ones.

The preceding observation draws its importance from the condition of the chest, and the intestines which were the source of the profuse hemorrhages.

The following observation of E. depends for its value, upon the cerebral symptoms: it is the cerebral form of typhoid fever.

E. M. took the fever the first of July last. At first the diagnosis was a little obscure. There was little headache, followed by lumbar pains, giving rise to the opinion that they were due to a simple cold, particularly as the morning remissions of fever were very marked. The diagnosis was well established upon the tenth day, when there was constant diarrhœa, distended abdomen, feebleness, stupor, etc., the fever became more intense, and continued with mutterings at night. Nevertheless, for several days the disease did not offer any complications. It was not until the fifteenth day that the fever became so intense and continued as to cause Dr. Lambron to use at first cold lotions, and afterwards cold affusions over the whole body in an empty bath-tub. These means produced no effect whatever. About the twenty-fifth day from the first appearance of sickness, I was called and found her in the following condition: Intense heat, pulse 130; temperature 41° C. (105.80° F.), appearance typhic, serous, yellow infiltration of the conjunctiva, intelligence gone, hardly recognizing those around her, diarrhœa persistent, bowels bloated, covered with rose spots, tongue black and dry, lips and nostrils fuliginous; taking no nourishment and refusing even cold drinks. Dr. Lambron gave an unfavorable prognosis, and did not think life could be prolonged beyond twenty-four hours, on account of the severe cerebral symptoms, the serous effusion of the conjunctiva, etc. An hour after my arrival I gave her a bath at 20° C. (68° F.) for fifteen minutes. After the bath, as well as at the moment of entering it, I made prolonged affusions upon the head with water at 10° C. (50° F.) and during the whole time of the bath I continued the affusions with the water of the bath-tub. The bath gave no unpleasant impression, and was not followed by a chill, the patient appearing completely insensible. She was put back into bed, simply dried and only covered with a sheet. Compresses wrung out of ice water were constantly applied to the head, the hair having been previously cut off. Before the bath I made her swallow a little wine: after the bath a few spoonfuls of warm broth. The temperature was at 39.9° C. (103.82° F.) having diminished more than one degree as the effect of the bath. Three hours after, another bath exactly like the preceding. Temperature before the bath 40° C. (104° F.), after the bath 39.2° C. (102.56° F.); cold compresses over the head during the intervals of the baths. Intelligence remains very obscure; she can hardly call the persons around her by name. Three hours after, temperature 39.9° C. (103.82° F.); another bath; after the bath 39.2° C. (102.56° F.), the bath always producing its effect. Following the bath a chill, which continued after the patient was put to bed and covered with a linen sheet, as the external temperature was very warm. In this bath the eye did not seem to be as bad, the intelligence was clearer, and she requested to be taken out of the bath. After each of these baths there was a discharge of urine and of diarrhœal matter.

For twenty-four hours the baths and the compresses upon the head were continued without any modification, unless it was when a few baths did not diminish the temperature much, as for instance, when it was 40° C. (104° F.) before, and 39.7° C., 39.8° C. (103.46° F., 103.82° F.) after; then the baths were given at 19° C. (66.1° F.) instead of 20° C. (68° F.), always fifteen minutes at a time.

The second day of the treatment, notwithstanding the continuation of these baths and of the cold compresses changed every five minutes at least, the cerebral symptoms continued to increase, every indication of intelligence completely disappeared, she could not be aroused so as to reply to any question, not even in the bath, but continued to mumble some incomprehensible words, the eyes closed, and the hands constantly occupied in drawing up her covering or seizing some imaginary object.

An inexperienced physician would have stopped the baths, observing the progressive aggravation of the symptoms. They were, however, regularly continued, with wine before and a few spoonfuls of soup after, which we were obliged to force her to swallow.

Dr. Lambron did not alter his opinion as to a fatal termination of the disease; still we had some reason to hope, for the bath held the temperature two hours out of three, that is, sixteen hours out of the twenty-four, at a relatively moderate degree. The pulse and

the respiration were good, the bowels slightly tympanitic. She took some nourishment. We then had some hopes.

The third day the carphologia and the muttering was replaced by a complete coma. During the next twenty-four hours the patient gave no sign of intelligence; the coma was absolute. The bath, the ice water poured upon the head did not for an instant arouse her from the deep coma; but the pulse and respiration were good, and she always passed urine after the bath. A bad symptom, however, was that she no longer took any food nor drink, the teeth were clenched, and if the mouth was forced open, liquids would remain unswallowed. This condition would have been very serious if it had continued, and would have necessitated the employment of the œsophageal tube for introducing food into the stomach.

Treatment continued with the same severity, and after forty-eight hours of anxiety, the patient, having taken twenty-four baths in three days, opened her eyes in the bath and recognized all about her. She seemed astonished to see me, and asked if she had taken the baths for any time, etc. From this day the intelligence was generally clear, there being only occasional moments of delirium, particularly at night, two hours and a half after the bath, when the fever returned. From this time also the quantity of wine and soup was increased. The baths easily producing a diminution in the temperature of a degree and a half, they were given again at 20° C. After even a week of treatment, the fever not reaching a temperature beyond 39.5° C. (103.10° F.), baths at 22° C. and at 21° C. (71.4° F. 69.4° F.) were tried, which produced the desired diminution. This treatment was continued another week, at the end of which time the temperature not reaching beyond 38.5° (101.30° F.), some of the baths were omitted, and their place supplied by enemata of water at 10° C. (50° F.), which often produced a little chill and always a slight diminution of the fever. Finally, three days later, the temperature being no higher than 38.5° C. (101.30° F.), the baths were relinquished and the cold enemata continued three or four times a day. Chicken, calf's brains, and other food was given, and convalescence began, which was not of long duration, taking into consideration the length and severity of the disease.

The foregoing are extremely serious cases of typhoid fever snatched from certain death by the method of Brand, although both were placed under treatment a long time after the commencement of the disease, one the fifteenth and the other the twenty-fifth day.

I could cite a great number of cases quite as severe, which I have observed and cured by this method. It is very certain that death would have occurred soon, for when the fever has reached such a degree, we cannot hope to save all. Instead of throwing the responsibility upon the method of treatment, we should rather fasten it upon the physician for commencing the treatment so tardily. When the treatment is entered upon at the beginning of the disease, or at least as soon as the diagnosis is established, not only are no patients lost, but all complications are avoided. I have had more than a hundred cases and no bad results. Some very conscientious observers have, however, had cases followed by death, even when the treatment was regularly pursued and commenced early. This is very likely, although I have myself never seen any. At any rate, these cases are very rare, and I guarantee that a fever, even the severest, treated from the moment the diagnosis is confirmed, will recover ninety-nine times in a hundred, and that even in those cases in which the complications have been permitted to arise, as in the two cases here given, they will almost always recover; only, the treatment should be pursued more vigorously and with greater exactitude and the patient watched more closely.

There is one point I cannot refrain from speaking of. In the two cases given, it is observed that the disease increased in severity the first two, three, or four days of the treatment by the cold baths. It is always so when the treatment is commenced late. It is well to know this, for otherwise the physician who is not thoroughly informed as to this method would become discouraged. This has often occurred at Lyons, and it would have been the case in these two instances, if we had not persisted in the method.

I repeat, in cases treated from the inception of the disease, complications do not arise. In my service at the *Hôtel-Dieu* of Lyons, I have had thirty-seven cases, thirty-seven recoveries; in private practice I have seen still a greater number, and no deaths. Among this number I have had some severe cases, treated late in the course of the disease; but the treatment by Brand's method has no contra-indication. I have had six cases of intestinal hemorrhage, eight cases of general bronchitis, two cases of pneumonia, three cases of diphtheritic angina; I have treated two pregnant women, the gestation following its usual course; two nursing women; two cases with a deep eschar. In fact, no contra-indication. The sooner the treatment is begun, the fewer the complications.

From the moment the diagnosis is made we begin the cold bath at 20° C. (68° F.), fifteen minutes at a time. The bath should diminish the temperature about a degree (2° F). This is the test: under these conditions, the bath almost always succeeds. If it diminishes it only five- or six-tenths, or for a still greater reason, not at all, as sometimes occurs in stout, fat persons, the next bath should be given at 19° C. (66.1° F.) or even at 18°; below that there is seldom any occasion of going. Again, if the bath diminishes the temperature from two to three degrees, as occurs in children of two, four, or eight years, or in very thin persons, the baths are then given for twelve, ten, or even eight minutes. It is requisite that the thermometer, placed in the rectum half an hour after the bath, and left there four or five minutes, should show a diminution of a degree C. This is repeated every three hours, while fever continues, as long as the temperature exceeds 38.5° C. (101.3° F.)

The fever continues as long in this method of treatment as by any other, only it is not complicated. The patient takes a little wine before each bath, and after each bath a little soup or other semi-liquid food. Between the bath, only ice-water or pieces of ice, especially if the tongue is dry, so that he is always fasting when he takes the bath. Before and after the bath cold water is poured upon the head, and in the interval cold compresses are kept constantly applied upon the affected organ or organs if there are any; upon the head, if there is headache or delirium, or epistaxis, etc.; upon the bowels if there is tympanitis, or diarrhœa, or hemorrhage (in the latter case bladders of ice are preferable); upon the chest if there is pneumonia. But if the treatment is commenced early, these precautions are most frequently unnecessary, the baths are all-sufficient, medicine useless; the diarrhœa ceases almost immediately, the bowels become supple, urine clear, stools natural and formed, and the appetite becomes keen. It is proper to resist this so long as the fever lasts and the baths are required, keeping to soups more or less strong, excluding meats until the baths are relinquished, and even then giving meat with great caution.

Towards the second or third week, when the fever is less intense, if the thermometer indicates a less degree, about 39° C. (102.20° F.), for example, the baths may be given for a shorter time, or less cold, and so continued if they produce the desired effect, that is to say, if they diminish the temperature a degree C. Finally, when the temperature is under 38.5° C. (101.30° F.) towards the end of the disease, omit the baths, giving the soup the same. Three hours after take the temperature, and if it exceeds 38.5° C. (101.30° F.) give the bath again; if not, give the soup and wait three hours.

The bath should always be given away from currents of air, and patients should be immersed up to the neck. (Given with these precautions, I have never known them to take cold.) Returned to bed, they should be wiped off gently, and covered lightly so as to avoid a reaction. If they are warmed by extra covering or by rubbing, the treatment would fail in its principal object, that of refreshing the patient during the greater portion of the disease.

Generally, after two hours and a half the cheeks become red, the temperature elevated, and the same condition exists as before the bath. Then another bath is prepared; we assure ourselves that it is at a proper temperature, 20° C. (68° F.); then we take the temperature of the patient, which is always increased, for the color in the cheeks, the restlessness, etc., never deceive.

After the bath patients often complain of cold extremities. There is no harm in wrapping the hands and feet in flannel, or even putting a bottle of hot water to the feet. Care should be taken, however, not to heat the rest of the body.

Patients also complain very much of the chill which they have towards the end of the bath, sometimes from the beginning, and which frequently lasts for an hour after being replaced in bed. It is painful to witness, but it is necessary to endure it, for it is a good sign, and if the bath does not diminish the temperature more than a degree, or a degree and a half, it should not be changed. It is absolutely necessary that the bath should produce the required effect. This chill is, however, the only disagreeable thing which occurs to the patient, while as a compensation he takes food during the whole of his sickness, often sleeps two hours and a half between baths, has no eschars, and almost as soon as the baths are omitted, whether upon the twentieth, thirtieth, or fortieth day, whether he has taken fifty baths or one hundred and fifty, or two hundred, as is sometimes necessary, the patient is capable of getting up and walking from one room to another, and ordinarily, if the weather is good, to go out within five or six days.

If fever is brought on by taking solid food, recourse should be had to the former semi-liquid diet, recommencing the use of meat after a few days. If there is constipation, enemata of cold water will almost always be sufficient to relieve it; if not, a little vinegar may be added.

This treatment is easy to pursue in all classes of society and is very economical. It is important to have a good thermometer and a good nurse. A moderate amount of intelligence is all that is necessary to make a good nurse, and as soon as the physician is sure of his nurse, he can *almost* leave the treatment to him.

THE MEDICAL REGISTER AND DIRECTORY OF THE UNITED STATES.—A new edition of this work is announced by its editor to appear during the present month.

CASE OF OTITIS EXTERNA DIFFUSA ET SUPPURATIVA, CAUSED BY INSPISSATED CERUMEN.

ALSO THE USE OF POLITZER'S AIR-BAG IN REMOVING A FOREIGN BODY FROM THE NASAL CAVITY.

BY J. OSCROFT TANSLEY, M.D.,

NEW YORK.

THE following case has nothing of especial interest above the ordinary cases of otitis externa, and of otitis media suppurativa, other than its causation, this being especially rare, and but little referred to in the records of ear cases. In fact I can, at the present moment, recall but one reported case, and that was by Dr. David Webster, in the MEDICAL RECORD, Vol. V., page 536, and reprinted in Dr. Roosa's excellent treatise upon the ear.

I desire to call especial attention to the condition of things which was the cause of trouble in this case, as it is one easily diagnosed by any person who is the possessor of an ear mirror and speculum, and is experienced in using the same. Had the attending physician previously skilled himself in examinations, so that he might have examined understandingly, and treated the case with syringe and warm water instead of the purgative pills which he gave to "relieve the stuffy feeling in the head," or the instillation of "laudanum and sweet oil to stop the pain, and improve the hearing," he would have prevented much unnecessary annoyance and suffering on the part of his patient.

Those who think it an easy matter to always diagnose correctly, will ascertain their error should they treat cases for a few months. I have seen a roomful of doctors, many of whom had been treating ears for several years, fail in making a diagnosis in the case of a man who had a piece of *red wool* in the external canal, and of which he could give no history. It was diagnosed as being a hæmatoma, blood in middle ear, etc., and there was considerable merriment when this "terrible affection" was extracted with a pair of angular forceps, to the entire relief of the patient.

The history of the case upon which the foregoing remarks are founded is as follows:

Delia L——, aged eighteen years, presented herself Monday, January 10, 1876, for treatment, complaining of severe pain, swelling, and loss of hearing in right ear.

History.—December 26, 1875,—that being fifteen days before,—had a sudden loss of hearing accompanied by tinnitus aurium in right ear. Ten days after she had severe pain, and the swelling began to show itself. Pain was very severe, and has continued unceasingly since. Never had any trouble with ears previously, excepting slight attacks of tinnitus in right ear and also in left, but to so slight a degree as to cause no especial discomfort.

Examination.—Right external auditory canal and ear considerably swollen, meatus nearly closed, and containing puriform matter; hearing distance $\frac{10}{48}$. Left ear, of which no complaint was made, was found to contain considerable amount of inspissated cerumen; hearing distance nearly, if not quite, normal. Eustachian tubes both easily pervious to the Valsalvian and Politzer's method of inflation.

Treatment.—Right ear was carefully syringed out with warm water, in which Sodii carbonas was dissolved, and considerable cerumen and some pus was washed out; by carefully using a small speculum a

view of the membrana tympani was obtained, and it was found to be covered with small pieces of exfoliated epidermis and cerumen, but no perforation was discoverable by any means of observation. After the syringing, although complete cleanliness was not secured because of the smallness and tenderness of the external canal, the hearing distance was increased to $\frac{10}{18}$.

From the left ear, although, as I said above, no complaint was made, a large piece of inspissated cerumen was removed, and hearing distance became more than normal.

Diagnosis of this case, which was seen by Dr. Webster, was inspissated cerumen becoming impacted December 26th, and causing otitis externa diffusa et suppurativa, by its presence as a foreign body January 5th. Advised to use aural douche with warm water several times a day, especially when there is pain, and be careful as to exposure.

Wednesday, January 12th.—The pain continued most of the night after removal of the wax, and then, as she said, "it broke," and the pain was relieved.

There is now a small perforation of membrana tympani; thus it is evident that the inflammation has extended into middle ear, and now there is otitis externa et media suppurativa acuta. Advised to still continue use of douche.

Friday, January 14th.—Pain not as great, only several times a day; there is no perforation to be found to-day. Inflates by Valsalvian method easily. A leech was applied, and patient told to continue use of douche as before.

Monday, January 17th.—Had considerable pain the day after last visit, but since has had no annoyance. Meatus considerably less swollen than when last seen, but contains small amount of pus. Hearing distance $\frac{10}{18}$.

Was syringed, and considerable exfoliated epidermis, which could not be removed without too much irritation; was found to obscure the view of membrana tympani. Tubes pervious to Valsalvian and Politzer's method. No perforation of membrana.

Monday, January 24th.—Ear very much better; swelling almost entirely disappeared; has no pain and considers herself cured, but I cannot get a satisfactory view of membrana tympani because of quantity of partially exfoliated epidermis obscuring the view, which I cannot remove with syringe, and do not care to try other means. Inflated by Politzer's method and instructed to still use douche.

Monday, January 31st.—External meatus contained a small amount of pus; says ear has been well until yesterday, when it pained considerably, but ceased last night. Was washed out and found to be generally much improved upon the condition of last week; meatus much larger and less tender, but membrane not yet of normal appearance. Advised to continue as heretofore.

Monday, February 7th.—Patient deems herself well, but the membrana is not yet in normal condition, and shows still lingering traces of inflammation.

Patient has not appeared since.

As a close, it is hardly necessary for me to say that, had this case not received the necessary attention, the affection would have passed on into otitis media suppurativa chronica, with the possibility of any of its serious consequences manifesting themselves at some future time.

FOREIGN BODY IN NASAL CAVITY.

I desire to call the attention of the profession to the use of Politzer's air-bag in removing foreign bodies from the nasal cavities, and will do so by citing the first case in which I used it.

A boy of about five or six years of age came to the clinic for treatment of otitis media suppurativa chronica, and after I had passed through the usual routine in such cases, I remarked that his eyes were red, and there was considerable lachrymation. I asked the cause, and ascertained that the day before the boy had in play passed a piece of *raw onion* up his nostril, and that his mother had tried various methods, among which was the use of a hair-pin, to remove it, but had been unsuccessful.

I could not examine with the forehead-mirror because of the child being so unmanageable, and the idea occurred to me that if I could produce a forcible current of air or water through the nares I could probably dislodge the foreign substance, and the posterior nares syringe and Politzer's bag suggested themselves as means to accomplish my object.

I used the posterior nares syringe, first to prepare the way by softening the secretions, and then Politzer's bag as usual, only taking the precaution to put the bulb-nozzle into the nasal opening which was known not to contain the substance to be dislodged, and also not to close the opposite nostril as is usual when the object is to inflate the middle ear.

I employed considerable force, for I feared I should not have the opportunity to make a second trial; and at the first attempt there was blown forcibly from the unclosed nostril quite a large piece of raw onion. The little fellow was pleased to see his enemy dislodged; and how he had been able to sleep the previous night with this extreme irritant to the Schneiderian membrane in his nose is beyond my comprehension.

This plan seems to be peculiarly applicable where the patients are young children, in which cases the use of forceps, spiral extractors, etc., without etherization, are usually next to impossible.

A CASE OF DISLOCATION OF THE HEAD OF THE RADIUS BACKWARDS.

REPORTED BY G. J. MACK, M.D.,

OF WATERLOO, IOWA.

PATIENT, a boy seven years of age, on the fourth of November, 1876, fell from a ladder, a distance of four or five feet, striking upon the floor. In what position he struck I do not know, as there were no bruises upon any part of the body to indicate, and the boy himself did not know. I saw the patient, with Dr. A. Middleditch, of this place, about three hours after the accident. Found him sitting in a chair, with the left elbow held away from the side slightly. Hand and forearm resting on his left thigh, and pronated. Any attempt to rotate forearm caused severe pain. The boy being quite spare, and no tumefaction having occurred at this time, the radius could be distinctly traced to a point posterior to the external condyle of the humerus. The form of the head of the radius could easily be felt, with the depression or cavity upon its upper surface. The dislocation was readily reduced by Dr. Middleditch, by making traction upon the forearm, flexed to a little more than a right angle; while the humerus was firmly held by being brought against his knee, and grasped above by me to fix it more firmly. After continuing the traction a few seconds, the head of the bone was pushed into its place by pressure of the thumb. Flexion, extension, and rotation were now perfect, and [produced

but little pain, with no apparent tendency to a re-dislocation. The form of the joint was also perfect. Right-angled pasteboard splints were then applied to the internal and external surfaces of the arm, and bandaged rather tightly. Since the accident, to the present time, two weeks, there has been no great swelling or soreness about the joint. Flexion, extension, and rotation are now perfect, only producing slight pain.

The original splints have been continued to this moment.

It may be proper to add that the dislocation was unaccompanied with any fracture or other complication.

Clinical Reports.

REDUCTION OF DISLOCATION OF FEMUR UPON THE DORSUM ILII; WITH REMARKS.

By DR. FRANK H. HAMILTON, M.D.,

AT BELLEVUE HOSPITAL CLINIC, NOV. 8TH, 1876.

M. J., æt. 33, a strong, muscular man, fell and dislocated his right hip, November 7th, 1876. He could give no account of the manner in which the accident had occurred, except that it happened upon the sidewalk, and when he was intoxicated.

Dr. Hamilton brought the patient before the class, about twenty-four hours after the accident, under the influence of ether, and stated that he had found him in the hospital, lying upon his left side, the thigh flexed to about 75°, and with the usual immobility. When brought before the class anæsthetized, the flexion of the thigh was found to be increased nearly to a right angle, but it was easily brought down to the same position as before the anæsthesia.

Attention was then called to the four principal forms of hip-joint dislocation, and especially to the signs which indicate a dislocation upon the dorsum. "The manner in which the accident occurs often furnishes presumptive, and sometimes conclusive evidence as to the nature of the injury, especially in determining whether it is a fracture or a dislocation. If this man had fallen square upon the trochanter major, it could not be a dislocation. The head of the femur lies so deep in its socket, that it is impossible that it should be dislocated by a direct blow. In order that this bone may be dislocated, it is necessary that the force be applied to the opposite extremity, and that it be thrown violently in such a direction as that it shall be converted into a lever. This law applies to the dislocation of most bones, and especially of the femur. Dislocation of the head of the humerus, however, constitutes a notable exception; since, in the case of this bone, the dislocation is quite as often caused by a direct blow upon the shoulder as by an indirect force acting upon its lower end. This is easily understood, when we notice the shallowness of the glenoid cavity, and the prominent and exposed position of the head of the humerus.

"We ascertain that this is a dislocation, then, without any knowledge of the precise manner of the accident; but having determined the fact of the dislocation, we are permitted to assume that it was not from a direct blow. The right thigh—which is the thigh here dislocated—must have been carried forcibly across the left.

"That it is not a fracture, we know from the position which the limb takes, and from the fact that it cannot be moved from this position, except in one direction, namely, of flexion. If it were a fracture, the limb would rest parallel with the other, or it could be easily placed in that position. In the case of this patient, the rigidity or fixedness of the limb remains even now, when he is completely under the influence of ether. As you see, the thigh can neither be abducted, nor rotated outwards, in any degree. We cannot appreciably increase the adduction; and we can only extend the limb a few degrees, or to about the same point at which we found it at the first.

"With regard to the amount of shortening in these cases, Sir Astley declared that the limb was sometimes shortened, in the dorsal dislocation, three inches; but Malgaigne declared that he had never found it shortened more than half an inch, and sometimes not at all, and he believed that the statements made by Sir Astley, and others, were due to errors in measurement. The most frequent source of error is, that one limb is measured flexed, and the other straight; and this alone may account for all the difference found in the opinions and statements of these two distinguished surgeons. Nevertheless, I am persuaded that, inasmuch as the shortening is due, in most cases, to a displacement backwards as well as upwards, the shortening does occasionally reach two inches or more."

Drs. Wood, Sayre, and Sabine, visiting surgeons to the hospital, were then requested to examine the limb. They all declared it a backward dislocation. Two of the gentlemen named thought it ischiatic; and one, with Dr. Hamilton, thought it was upon the dorsum ilii. Opinions were therefore equally divided. Dr. Hamilton stated, that the fact that the limb was more flexed than is usual when the head is upon the dorsum, might be explained by the position which the patient occupied; if he were standing, probably the limb would become much more extended. He further remarked, that a difference of opinion on this point was frequently found to exist among surgeons of equal experience, after a careful examination; thus proving how difficult it was, sometimes, to say whether the head was upon the upper margin of the ischiatic notch, or higher up, and fairly upon the dorsum; but he believed this to be upon the dorsum. Fortunately, however, it was not of much practical importance to decide this question, since in either case the mechanism of the reduction, by manipulation, was about the same. The chief point of difference being, that when the head was in the ischiatic notch, there was more danger of carrying it around the lower margin of the acetabulum into the foramen thyroideum; and it was necessary to be more careful, in flexing the thigh, not to throw the head too low down.

"I will remark," said Dr. Hamilton, "that this patient has taken ether. In nearly all my surgical operations I prefer ether to chloroform, as being equally efficient and more safe; but in the reduction of dislocations we need complete muscular paralysis, and this is much more quickly and certainly attained by chloroform than by ether, and I am in the habit of using chloroform in the reduction of dislocations; but I am informed that the Commissioners have lately forbidden its use in this hospital."

Dr. Hamilton then stated that he would proceed to attempt the reduction: *first*, by gentle and very guarded manipulation—a method which has often succeeded, and which causes little or no additional lesion to the capsule. If this failed, then, *second*, he would resort

to violent or more forcible circumduction, by which additional injury would probably be inflicted upon the capsule. If this failed also, he would then, *third*, try extension, as recommended and practised by Sir Astley Cooper.

Reduction.—The patient resting pretty fairly upon his back, Dr. Hamilton, standing upon the right side of the patient, *first*, took hold of the dislocated limb (which was large and powerful), by placing the palm of his left hand under the knee, and grasping the top of the ankle with the right hand. The leg was brought to a right angle with the thigh, and the thigh flexed to a right angle with the body the whole limb being still in a position of adduction and inward rotation. When the thigh reached the position of a right angle with the body, there was evident resistance, indicating that it could be carried no further in this direction without the application of considerable force. *Second*, the thigh was abducted moderately, or as far as it could be carried without force. Attention was called to the fact that even this amount of abduction was impossible when the thigh was in the position which it occupied before the manipulation was commenced; but the abduction did not exceed eight or ten degrees, and was not sufficient to elevate the thigh to a perpendicular line—indeed it was considerably short of this position. *Third*, the whole limb was rotated outwards; and here was the first point of delay in the process of manipulation. During a few seconds no further progress was made toward reduction; but the position was steadily maintained by continued forcible rotation outwards. Dr. Hamilton remarked that he felt no yielding of the bone; but this observation had scarcely been made, when the head suddenly slipped into its socket, and the limb fell, with a peculiar oscillating motion, upon the table, parallel with the sound limb.

To the applause which immediately followed the reduction, Dr. Hamilton responded as follows:

"Gentlemen, I accept the applause as a tribute to Science, but not to myself personally as having displayed any especial skill in the reduction. Any one of the distinguished gentlemen present would have been equally successful; and I have no doubt that, now that you have seen the method, you will succeed also, if ever you have occasion to try it. Let no one say that surgery makes no progress. It is true that this method is probably very old. Hippocrates described very briefly how we might sometimes reduce a dislocation of the thigh, by bending the limb at the joint and making rotation; and many other surgeons, from time to time, have, more, or less, perfectly described this mode of reduction; yet it was so little known to surgeons generally, that even Sir Astley never alluded to it in his Treatise on Dislocations and Fractures near the Joints, nor in any of his other writings. Professor Nathan Smith, of New Haven, practised this method; and in the volume published by his son, Professor N. R. Smith, of Baltimore, the method is described with great fidelity, and is illustrated by drawings. Notwithstanding all this, to the late Dr. Read, of Rochester, N. Y., the profession and the world are indebted, mainly, for our present knowledge upon this subject; since he again drew our attention to it, and succeeded in demonstrating, to the complete satisfaction of all, by a number of cases, its great superiority over every other method. When, however, he was reminded that Dr. Nathan Smith had described and practised the same method, that many others had done the same, and that he could not, therefore, claim, strictly speaking, the original discovery, he refused to concede this point; claiming that Nathan Smith had directed the limb to be carried up abducted, which, he affirmed correctly, was impossible; but he evidently misunderstood Dr. Smith, who had only said that the thigh must be *slightly* abducted, by pressing the knee outwards while it was being flexed; and this advice was given in order that the head of the bone might be kept near the posterior lip of the acetabulum. This may be, and we think it is, unnecessary, but it does not affect in any way the principle of the reduction.

"I wish to call your attention again to the fact that, in effecting reduction, the thigh was only moved in those directions in which it could be easily moved. It could not, at first, be abducted or adducted, or extended. In all these directions it was nearly or quite immovable. It could, however, be flexed easily to a right angle with the body; and this was the first thing done. Dr. Read declared that the thigh must be flexed until the knee touched the belly; but I have never found this degree of flexion necessary, except in old dislocations. Nor is it proper, in recent cases, to make this extreme flexion, unless moderate (right-angled) flexion has failed, since it increases the laceration of the capsule, renders liable a displacement of the head of the bone into the foramen thyroideum, and endangers a fracture of the neck of the femur. When the thigh-bone had arrived at a right angle with the body, a slight abduction became practicable; and now the head of the femur, situated behind the acetabulum, was ascending the inclined plane towards its posterior lip or margin. Steady and forcible rotation outwards, of the knee and thigh, finally carried the head into the socket. This might have been facilitated by lifting the knee, or by a slight rocking motion, as first described by Nathan Smith; but neither of these aids were required in this case."

Before the patient was removed, a small pillow was placed between the knees and the legs loosely tied together, to prevent a re-luxation.

Immediately following this case, an old lady was presented, whose shoulder had been dislocated a few days before, and had been promptly reduced by Dr. Hamilton's senior house surgeon, Dr. G. B. Hope; and a second case of old dislocation of the shoulder in a man was also introduced. Both of these shoulder dislocations were caused by direct blows, and served to illustrate the remark previously made that, in regard to the causation, the same law does not apply to the shoulder as to the hip.

Note.—The man whose thigh was reduced walked without limping, on the fourth day after the reduction, and ascended the five or six flights of stairs to the amphitheatre on the seventh day—walking in the presence of the class and declaring that he felt no soreness or pain in the thigh. This was done without authority from any one, and was doubtless injudicious; but it served to illustrate how little injury reduction, by manipulation, sometimes causes to the parts in and about the joint.

Progress of Medical Science.

Ligation of both Femoral Arteries. The following interesting case is reported by Dr. Erskine Mason: John McGuire, aged 23, a milk-cart driver, was admitted to St. Luke's Hospital, September 2, 1870, with popliteal aneurism of the right leg. The patient had had pain in the limb for two or three months, but first discovered the pulsating tumor about

ten days before entering the hospital. On September 7th, an incision four inches in length was made at the apex of Scarpa's triangle, and the sheath of the femoral vessel exposed. A corps of assistants was then organized, and digital compression was applied to the artery and kept up uninterruptedly until the next day, when the tumor was firmer, and the pulsation and bruit had ceased. The compression was now interrupted for five minutes every half-hour, but as the pulsation and bruit reappeared at midnight, continual compression was resumed and kept up till noon on September 9th. The compression was kept up at intervals until September 14th, when it was discontinued, the pulsation and bruit having almost disappeared. The tumor was subsequently treated by a compress and sharp flexion of the leg. On October 8th, the patient was discharged at his own request, but was directed to keep up the flexion at home. The pulsation had disappeared some time previously, but a faint bruit was still audible. On October 17th the patient was readmitted to the hospital, the tumor having increased in size and pulsation returned. On the 18th, the femoral artery was exposed in the upper part of Scarpa's triangle, and digital compression applied. The patient, however, did not bear the compression well, and on the next day the artery was ligated. He was subsequently discharged cured. The patient had been under the care of Dr. Gurdon Buck.

On June 12, 1872, the patient was admitted to Roosevelt Hospital, suffering from an aneurism of the left femoral artery in the lower third, just before the artery enters Hunter's canal. This aneurism had made its appearance about three months previously. The circumference of the tumor was twenty and a half inches. Bruit, thrill, and pulsation were well marked. A hard, apparently solid mass, the remains of the first aneurism, was found in the right popliteal space. As the patient decidedly objected to any attempt at compression being made, Dr. Mason ligated the left femoral artery in the middle third, on June 22d. The ligature came away on July 10th. On August 6th, the size of the tumor was eighteen and one-quarter inches, and the patient was discharged cured.—*Archives of Clinical Surgery*, September.

The Alterations in the Mucous Membrane of the Stomach consecutive to Cerebral Lesions.—According to Brown-Séquard, softening and ulceration of the gastric mucous membrane occur after injuries of the corpora striata, of the crura cerebri, and the spinal cord; hemorrhages, on the other hand, follow injury of the pons Varolii at the point of insertion of the middle peduncle of the cerebellum. Hemorrhages do not result from paralysis of the vasomotor nerves, but on the contrary they are preceded by contraction of the arteries and veins, and consequent distention and rupture of the capillaries.—*Centralblatt für Med. Wissenchaften*, September 16th.

Solution of India-Rubber in local Treatment of Psoriasis.—Mr. Wyndham Cottle has found this material useful in chronic cases of psoriasis, where there is an excessive formation of dry scales, especially in the neighborhood of the joints, where the scales form crusts, are hard, and render the movement of the part painful. The crusts and scales being removed and the absence of grease insured by wiping the parts with ether, and the skin dried, a solution of the india-rubber is applied with a brush and the application renewed as often as is needful to maintain a continuous covering over the affected skin. He recommends a solution composed of india-rubber half an ounce, and chloroform eleven and a half ounces. He has met with more rapid recovery in these cases by this application than by the ordinary local measures, from the fact that these coverings prevent evaporation and hinder the loss of the natural perspiration of the part. He thinks the same treatment is applicable to some conditions of chronic eczema.—*The Lancet*, September 30, 1876.

Anæsthesia of the Larynx before Operations.—The laryngoscopist will sometimes meet with patients whose sensitiveness is so great that it cannot be overcome even by the greatest skill and patience, and in other cases he may be so pressed for time that he will be unable to wait for the production of tolerance in the usual way. For these cases the method of producing laryngeal anæsthesia invented by Türck, and perfected by his pupils, especially by Schroetter, is peculiarly adapted.

When, for instance, the surgeon desires to operate on the following morning, he must begin at seven o'clock in the evening to touch the laryngeal mucous membrane twelve times in succession with a brush dipped in pure chloroform. This will excite an intense congestion of the membrane, and thus place it in the most favorable condition for absorption. At eight o'clock, one hour later, a brush dipped in a saturated solution of acetate of morphia must be plunged twelve times in succession into the larynx. The patient should avoid swallowing during this time, and as a sort of antidote should rinse out the mouth and throat after each application with a gargle composed of two parts tannin, three parts alcohol, and forty parts water. Towards midnight the patient should be visited, so as to be certain that there is no morphine poisoning. At seven o'clock in the morning the larynx will usually be found to be insensible, and the operation can be performed. If the insensibility be incomplete the local applications should be repeated twelve times, and so on every hour until the desired end is attained. If opium poisoning should occur, it can be easily overcome by the usual methods, but it can almost always be prevented if a proper surveillance of the patient be maintained.—*Lyons Médical*, October, 29, 1876.

Antidote for Gelsemium Poisoning.—Dr. George S. Courtright, of Ohio, was called to see Dr. Stephen Bennett, a brother practitioner, whom he found in the following condition: The head falling forward, the chin resting on the breast, respiration slow, pulse 100, face congested, and lips of a livid color. He could move the tongue slightly, but was unable to articulate freely; the pupils were dilated and insensible to light, and there was paralysis of the lower jaw. From the symptoms the doctor decided that it was either gelsemium or belladonna poisoning. Emetics were given without success. Morphia in solution (one-half a grain), was then injected into the arm, and repeated in three minutes. Three minutes later there was a slight improvement in the breathing. Four minutes afterwards an equal amount was again injected, and two minutes after he raised his arm slightly; the pupils were now a little contracted. In another four minutes an equal amount was injected and one-half a grain given internally. During all this time the head had to be held up to allow air to enter the lungs. In six minutes another injection was given, from which time no further medication was employed, and in two hours the patient was able to talk, and prove pretty conclusively he had taken gelsemium by mistake.—*Cincinnati Lancet and Observer*, November, 1876.

CONTAMINATED AIR IN OUR DWELLINGS.

THE liability to contamination of the air in our dwellings seems to increase in proportion to the number of so-called conveniences of construction and arrangement which advanced civilization has made necessary. For instance, the attempts to perfect a system of sewerage in our large cities bring in their train dangers which in times past were never thought of. The modern contrivances of water-closets, sink-drains and the like, instead of causing the effectual and rapid disposal of house sewage, invites the escape of sewer-gas itself into every department of our dwellings. How to prevent the latter has become one of the most important questions of the hour. There is no doubt that a great deal can be done by intelligent householders to this end, by the construction of proper traps and by the establishment of proper sewer connections. Cases in which this is done are, however, so much in the minority, that their example has no appreciable influence upon the interests of the community at large. The difficulty is to comprehend what is really meant by the proper construction of traps and the maintenance of their proper condition. Too many believe that when the water-closet and main sink-pipes are protected, nothing else is required. Far from this being the case, we have found that a greater danger and more direct avenue for sewer-gas exists in the arrangement of the wash-bowls. The great majority of these are without any protection whatever, and there is such a constant liability for the escape of noxious vapors into the bed-chambers themselves, that it is a wonder how so many can escape the effects. The directness of communication of these pipes with the sewer was manifested in a very appreciable manner in many of the houses during the recent scarcity of water, when the traps which did exist were allowed to become dry. It is, however, absurd to suppose that a mere trap for the escape-pipe of a wash-bowl is a protection against danger when the overflow pipes still maintain a direct communication. Prudent physicians, knowing the great liability to the omission of the trap precaution in these outlets, are accustomed to cover them with wet towels, or by some other method which may be equally effective.

The necessity for frequent change of water in even perfect traps is forced upon us by the recent observations made by an eminent London sanitarian who has shown that the poisonous gases are prone after a time to saturate the water in such traps, and afterwards to escape above them.

Allowing, however, that every known precaution is taken in regard to traps and other appliances, there is no absolute security against sewer-gas when there is a sufficient pressure from below. The ventilating sewer-pipe would appear to offer, theoretically at least, the best chance for overcoming the latter. To a certain extent it accomplishes such a purpose, that is to say, when the pressure from below is extreme. In the great majority of cases, however, the ventilating tube contains a column of stagnant air, and for purposes of ventilation amounts to nothing. We certainly could not expect it to be otherwise so long as there are no provisions made for creating and maintaining an upward current through the tube. Even if the contrary were the rule, and these pipes were of real service as ventilators, there is such an objection against their manner of introduction by the Health Board on the part of property-holders, that this so-called system of ventilation can never become popular. No one doubts that the main sewers should be relieved as much as possible; but this is so obviously the business of the authorities, that the citizen as a private individual has really nothing to do with it. It is well known that the general sewerage of the city is not what it might be. The sewers built by sections have different grades, and favor stagnation of their contents, especially during the times when the water supply is not abundant. This, however, is no reason why the citizen should be compelled at his own expense to ventilate the sewer through his house. Aside from their being demonstrably ineffective, these measures of the Health Board are positively unfair, and have a tendency to excite a prejudice against sanitary reform among a class whose co-operation is of the greatest importance. But this is merely a remark in passing, to urge a more feasible plan of ventilation of the main sewers.

Not long since, a practical engineer suggested the construction of tall ventilating shafts in different parts of the city, by means of which the noxious gases could be allowed to escape directly from the street sewers far above the tops of the tallest houses. Such shafts properly constructed would doubtless answer every purpose. On general principles, at least, the system would have many strong recommendations in its favor, not the least of which would be the repeal of the present obnoxious, not to say tyrannical regulation of the Health Board. Aside from these objec-

tions, the present method of ventilating the sewers is calculated to give an idea of security to the ignorant householders, which in the present state of sanitary science is altogether unwarrantable. The principles involved in the protection of houses from contaminated air apply with still more force to those in rural districts, where the trap system is in its infancy and where the rudest contrivances for drainage are the rule.

While upon the general subject of contaminated air in our houses, we must not lose sight of the bad influence of the modern hot-air furnace. Convenience of construction and management have compelled us to place this apparatus in the cellar from which all the so-called fresh air is supplied for heating purposes. How much of really pure air can be obtained by these means is a question not difficult to answer, and yet modern civilization congratulates itself on having solved the problem of properly heating our dwellings. We are not aware that the hot-air furnace as ordinarily found in our houses has ever been directly associated in the minds of physicians with the cause of any particular class of diseases That this relation has not been made out before has not been from want of opportunities for observation and study. Cellars, as a rule, are damp and unhealthy, are the receptacles of stagnant and impure air, and oftentimes contain cesspools which are intended to supplement imperfect drainage. But even if every precaution is taken to guard against the ordinary objections, and every effort is made to supply the air to the furnace directly from the outside, the low level of the supply-shaft is such as to draw in the air from our filthy gutters, our indifferently kept streets, and in addition the sewer-gas which escapes at this level from the culverts. Next then to the sewer-pipe itself, the hot-air furnace may be considered as the most convenient contrivance of our times for endangering the health of the occupants of houses which have the usual "modern improvements" Although there are many other causes for contaminated air in our dwellings, these are perhaps the most important, and seemingly the most difficult of prevention. How to entirely overcome them is so much an open question, that for the present at least we have only to study, to labor, and to hope.

PRESCRIBING DRUGGISTS.

The Chemists and Druggists' Trade Association, of London, have passed a resolution, to the effect that in any case in which a chemist and druggist is threatened with legal proceedings for recommending simple remedies, when required to do so, in his own shop, it will undertake to defend him. Practically speaking, then, the London physicians are no better off than we are. Although they may be protected by a law calculated to punish such as infringe upon their professional rights, they are met with a determined resistance from the opposite side. The right to prescribe simple remedies in one's "own shop" is to be defended in the face of an explicit law to the contrary. Of course a great deal must depend upon the technical interpretation of what simple remedies may be, where in fact the line is to be drawn between the apothecary and the practising physician. If any definite distinction can be made between the two, it doubtless will be a source of gratification to the practitioner to know that, beyond a certain point, he is possessed of rights and privileges which even the ambitious and enterprising counter prescriber cannot question. At best it must be a matter of conscience with the apothecary, which, from a business point of view, amounts to very little.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Anniversary Meeting, Nov. 16, 1876.

Dr. S. S. Purple, President, in the Chair.

The twenty-ninth anniversary meeting of the New York Academy of Medicine was held in the Academy Hall on Thursday evening, November 16, 1876, commencing at eight o'clock. The exercises were opened by prayer by Rev. Dr. Ormiston.

Dr. W. T. White delivered the anniversary discourse, which consisted of a brief review of the advance that had been made in medicine during the past century, and especially the achievements which had been made by the profession in this country. The subject naturally gave rise to two questions: 1. How far had the great body of facts brought forward the progress made in the domain of physiology, chemistry, pathology, hygiene, etc., rendered the way more clear, and the means more perfect for the amelioration of human suffering and the cure of human maladies? and 2. By what instrumentalities and methods had such knowledge been promoted and diffused; in other words, how far had the progress in medical science been taught to the entire profession? The latter question was first considered, and the chief means for the promotion of medical knowledge were noted under three heads: 1. Medical Schools; 2. The Medical Press; 3. Medical Societies.

In a review of the history of medical colleges in this country, it was found that the first medical diploma conferred in this country was conferred upon Robert Tucker, in New York, in May, 1770. At the close of the eighteenth century 220 candidates had graduated from medical colleges in this country. At the close of the revolutionary war there were two medical colleges, and the increase had been to 84, of which about 60 were in operation last winter, with an attendance of 6,620 students, and a graduation list numbering about 2,200. The time was when the medical student pursued a two or three years' course of study in the office of his preceptor, and entered upon the practice of his profession without ever having had the slightest hospital experience or the opportunity to listen to a lecture in a medical college. To-day, however, with all the advancement made, the standard of medical education was not as high as it should be, and the colleges should demand a more thorough and extensive preparatory study. It was for the colleges to institute such a medical reform, but an obstacle

was met in the fact of so much competition among the colleges, each being interested in graduating as large a class as possible. To overcome the obstacles and secure the best men for graduation, it has been proposed either to have a board of examiners appointed, which should act independently of all medical schools, or to lengthen the term of college study one or two years. If either of these methods could be adopted it would make a good beginning, the faults of the present systems would gradually pass away, and the results would be beneficial both to the profession and to the public.

The medical press had been one of the most efficient means for the spread of medical knowledge, and had been growing in activity until at the present time 286 regular medical journals were published. Of these about 46 had an existence in this country, and were the sole survivors of 198 that had been commenced. The first medical journal was published in Great Britain in 1796, just one year before the *Medical Repository* was established in New York.

Medical journalism had accomplished an important purpose in the promotion and diffusion of medical knowledge, but its mission was still more important than it had been.

The influence upon the progress of medical science due to the organization of efficient medical societies was next considered. They had fostered a better social and professional feeling, were productive of good results when well managed, and by a united action were able to hurl aside the mischievous effects of empiricism. The oldest medical society in this country was established in the State of New Jersey in the year 1766—The New Jersey State Medical Society. In 1847 the American Medical Association was founded, and from it had emanated a code of medical ethics which was beneficial in holding in restraint those who otherwise would be disposed to become irregular, although the code was not by any means perfect.

The discoveries in medical science made during the past one hundred years formed the next topic of the discourse, and special mention was made of those which had their origin in this country. It was a notable fact that whatever advance had been made in organic chemistry, in physiology, in surgery, and in every branch of medicine and its kindred sciences the world over, had been accomplished by the labors of men belonging to the regular school.

Within the past twenty or twenty-five years there had been a tendency to the study of special departments, and a concentration of observations upon some single subject.

The germ theory of disease was alluded to, and although all the opinions had not been true, the faulty ones would destroy each other and assist in placing the doctrine upon a more sure foundation.

The progress in surgery had been increased by the four years of our late war, and the advance in that department had also been especially assisted by photography.

The society for the prevention of cruelty to animals was not passed, and it was believed that its workers had overleaped the limits of usefulness by a spurious zeal and an imaginary benevolence. If the well-meaning men were better informed, they would know that the physiological experimenter avoided the infliction of unnecessary pain.

To Dr. John Stearns, the first President of the New York Academy of Medicine, was due the introduction of ergot as a therapeutical agent, and to Dr. McDowell, of Kentucky, was due the credit of first performing ovariotomy, an operation which since its introduction had been the means of saving the lives of two thousand women. A century ago, gynecology was scarcely known. In no other country had such distinct lines been drawn between the regular profession and the numerous avocations which did not belong to it, and it was one of the intentions of the New York Academy of Medicine to afford a means for distinguishing between the regular and irregular medical practitioner. "There had ever been a readiness to recognize faith in the medical heart among all conditions of men, but that faith had been purest and deepest when medical societies and science had been best cultivated in their several departments for the welfare of human beings."

Dr. Barker moved that the Academy extend a vote of thanks to Dr. White for his cool, cautious, and temperate relation of facts, and the excellent taste manifested in his discourse by avoiding everything like extravagant pretension or claim. The motion was unanimously adopted.

The Academy then adjourned.

Correspondence.

IS ALCOHOL A FOOD?

To the Editor of The Medical Record.

Sir:—In order to answer the question that caps this article, we must first decide what we understand by the term "food."

What, then, is a *food?*

Physiologists generally agree in defining it to be any substance which furnishes to the body constituents necessary for its alimentation, or prevents their removal. The purposes which foods serve in the economy are chiefly to generate heat and to produce and maintain the structures under the influence of life and exertion. The physical effects of the ingestion of food are mainly:

I.—*Increase in the exhalation of CO_2.*

II.—*Increase in the force and frequency of the pulse.*

III.—*Increase in the bodily temperature.*

IV.—*Diminution in the amount of urea eliminated.*

The evidence that ingesta are nutritious, is that, being consumed in the body, they are not found in the excreta in disproportionate quantities.

To recapitulate. Foods generate heat, maintain functional power under exertion, this action being carried on chiefly by three elements: O, H, and C. The effects of ingestion are increase in CO_2, pulse and temperature, and diminution of urea. Foods are used up in alimentation not appearing *sui generis* in the excreta.

Alcohol has a twofold action on the economy, varying with the quantity ingested. It may be defined as *constructive* and *obstructive*. The first representing its non-narcotic or purely food action, the second its narcotic or poisonous action, under the influence of which, paralysis of the sympathetic takes place and various vital processes are deranged.

In claiming for alcohol nutritive power, we must be understood as limiting the term to its use in such doses as stop short of the characteristic physiological manifestations of the drug. When, however, the line that separates the non-narcotic *constructive* action from the narcotic *obstructive* is once ove stepped, then does alcohol cease to be a food and becomes a poison.

It will be certainly unnecessary to take up your

valuable space sufficiently to quote fully the experiments which substantiate that alcohol, in its action limited as above, is as truly a food as the amylacea or albuminoids, it will be sufficient to merely allude to them, as they are within the easy reach of all.

Alcohol in *constructive* doses, in common with other foods, *increases the elimination of* CO_2 (substantiated by the experiments of Dr. Edward Smith, and given in his work on Foods); *increases the frequency and force of the pulse* (proven by the elaborate experiments of Parkes and Wollowicz upon man with the sphygmograph); *checks the elimination of urea* (shown by the experiments of Dr. W. A. Hammond upon himself, and confirmed by Parkes and Wollowicz); is *not* found in the excreta in more than very limited quantities (supported by Baudot, Schulinus, Anstie, Thudichum, and Dupré). Further than this, the experiments of Dr. Ford in demonstrating the presence in the blood of alcohol as a result of the disintegration of the hepatic sugar, confirmed by Dupré and Béchamp, *the generation of heat, and so force*, proven by Dupré by convincing experiments, completes a chain of evidence most strong, and is a sufficient refutation of the argument of those who, either through scientific obtuseness, or a mistaken zeal in the cause of temperance, obstinately shut their eyes to the results of careful and exact research. As a late correspondent of yours from Orange, Mass., denies that alcohol should rank among the heat-producing foods, I would like to refer him to the testimony of Dupré in the *London Practitioner* for 1872, Vol. IX., page 33. Dupré here demonstrates that "one gramme of alcohol oxidized in the body evolves 7,184 units of heat, while the same weight of lean beef gives off only 1,482 units of heat. 9.3 ounces of lean beef, equal to about two ounces of alcohol, will supply enough force to keep up and maintain for one day the circulation and respiration of an average man, *i.e.*, four ounces of strong spirit will suffice for this purpose."

The modest statement of your correspondent, that had Dr. Anstie lived to this day, he would have suffered his principles to undergo a radical change upon this subject, is too purely gratuitous for serious notice.

Halsey L. Wood, M.D.

62 North Street, Auburn, N. Y., Nov. 13, 1876.

To the Editor of The Medical Record.

Dear Sir:—Under the above caption, Dr. Stimson, in a previous issue, refers to my communication on the same subject, and says that "Dr. Mays seems to desire to support the theory that alcohol is a food," and then asks, "Does it (alcohol) contain those elements which replenish the tissues of the body," and after alluding to the teaching of organic chemistry, he decides this question in the negative. Again, he asks, "Is it then a force, supplying food?" This he answers with an emphatic "No," and in order to substantiate his refutation of the last question, he further says, "Hydrocarbons produce force by oxidation. Alcohol is a hydrocarbon, and, if consumed in the body, *must produce heat* (the italics are ours) in order to rank among the heat-forming foods," and he then refers to the experiments of Dr. W. B. Richardson, of Edinburgh, which, he says, "go to prove that instead of producing animal heat, it diminishes the heat of the body."

Now, with the first conclusion at which the Doctor arrives, we have no reason or disposition to find fault; but with regard to the second we will say that it would be true if heat was the only force generated by foods in the body, but that it would be a most fatal and unscientific test (with which he assumes to decide whether or not alcohol can be classed among those substances which have the capacity to generate bodily force), were he to apply the same mode of reasoning to other hydrocarbon foods, the force-producing power of which no one doubts. For if the distinguishing characteristic of a hydrocarbon food exclusively depends on the expenditure of its force in the shape of heat while undergoing oxidation in the body, what then becomes of fat, starch, and sugar; one gramme of each, according to Prof. Frankland, has the capacity to produce 9,069, 3,912, and 3,348 heat units respectively, when oxidized outside of the body. ("Each heat-unit represents the heat required to raise one gramme of water 1° Cent. or 1.8° Fahr.") In other words, this means that by the oxidation of one pound of beef-fat, a sufficient amount of heat is generated to elevate "the temperature of 9,069 lbs. (about 4 tons) of water 1° Cent. (1.8° Fahr.); that the oxidation of the same quantity of arrow-root will similarly raise the temperature of only 3,912 of water," etc. (Pavy, "Food and Dietetics.") Now it is very evident that the energy which these substances possess cannot be solely expended in the production of heat while undergoing oxidation within the body, for if this were the case the heat of the body would be raised to a degree incompatible with life, whereas the truth is that the temperature of the body after the ingestion of a meal is elevated to but a slight, and sometimes to an inappreciable degree. Nor indeed is this latter view at variance and inconsistent with what we would be led to anticipate from our knowledge of what is required to carry on the processes of nutrition and oxidation in the body, for we know that there is other work to be performed in the animal economy besides that of maintaining the bodily temperature at a certain uniformity.

The physiologic facts are these: All our hydrocarbon and carbohydrate or force-producing foods are oxidized within the body, and the force or energy which they possess, and is thus set free, is destined to perform "interior work," such as nervous muscular and other work. Now it is a physical axiom that that force which accomplishes nervous, electric, chemical or mechanical work cannot manifest itself as heat-force at the same time. Hence it is an obvious absurdity to hold that a substance cannot be a force-giving food merely because its force does not appear in the same form within as it does when oxidized outside of the body. There is no doubt that alcohol in certain quantities behaves in the very same manner within the organism as do other foods of the same nature; if not, then it is the most extraordinary and exceptional substance in existence, for Drs. Anstie, Dupré, and others have proven that the body is capable of consuming one ounce and a half of alcohol, thus setting free a larger amount of force than do most of our other force-yielding foods, and this view is in perfect accord with the ideas of the late and much lamented Dr. Anstie, as expressed in his "Final Experiments on the Elimination of Alcohol," published in the *Practitioner*, (vol. xiii.) as follows: "I think I may take it as conceded that quite 600 grains of absolute alcohol can be disposed of daily within the organism of an adult male without any perceptible injurious effect upon the bodily functions. Now, this quantity of alcohol is (theoretically) capable of generating an enormous amount of force; but it is equally certain that that force does not show itself under the form of heat."

If space permitted, we could detail the conclusions

which we are warranted to draw from scientific data concerning the kind of work which alcohol performs within the body, but we have no desire to encroach, and, therefore, beg leave to refer to a paper entitled "The Principles of Antipyretic Action," which we are preparing, and will be published shortly, in which this phase of its action is discussed, not only in relation to the manifestation of its energy in other than heat-force, but also its power to reduce the bodily temperature under certain circumstances.

It is a lamentable indication of the present state of therapeutics (if such logic can be taken as a fair specimen) that a person who desires to give an intelligent and scientific expression of his views should erroneously substitute the toxic for the therapeutic action of a substance, and allow his ideas to be governed to such an extent by the one-sided and inadequate experiments and conclusions of Dr. Richardson, as to believe that they are finally decisive on the alcohol question. For any one who has given any attention to this subject must know that the four stages into which Dr. Richardson divides the action of alcohol are but the "progressive changes" of the effects of alcohol in narcotic and poisonous doses, and have nothing in common with the action of alcohol in small and dietetic doses. The effects from the first to the last as noticed by Dr. Richardson and quoted by Dr. Stimson, are produced only by large and unoxidizable doses of alcohol, and are directly the reverse of those which are produced by small and oxidizable quantities. It would be just as unfair to represent the emetic action of ipecacuanha as the only therapeutic effect of this remedy, when the truth is, that in certain circumstances and certain doses it is also anti-emetic; and the same holds true of many other substances which have a twofold action on the human body.

Dr. Stimson would certainly be very welcome to the gratuitous assumption that Dr. Anstie would probably have reached similar conclusions to those of Dr. Richardson, "had not his useful life been cut short as it was;" and it would appear more graceful, were it not known that Dr. Anstie described those identical effects of alcohol in a very comprehensive and scientific manner in his "Stimulants and Narcotics," nearly twelve years ago.

Sincerely yours,

THOS. J. MAYS, M.D.

UPPER LEHIGH, PA., Nov. 15, 1876.

A CURIOUS CAUSE FOR VOMITING IN AN INFANT—A BRASS RING HOOKED OVER THE EPIGLOTTIS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I send you the following case for publication, if you think it will prove of sufficient interest to your readers.

One morning during the last week in October a little child, eleven months of age, was brought to my office for advice. The mother, an intelligent American lady, told me that the infant had been perfectly well up to seven o'clock on the previous evening, when it was suddenly seized with a slight attack of vomiting, and since that time it had refused the breast. She also said that she had lost a child with diphtheria about two years ago, and she now feared that this one had something the matter with her throat, because she would not nurse. The child was sleeping quietly in its mother's lap when I commenced my examination. There was no dyspnœa, and no increase in the normal frequency of the respirations. The pulse was regular in force and action, the skin was cool and natural, and, as far as I could judge from external signs, there was nothing wrong with the child. Upon inquiry I could elicit nothing which would explain the symptoms that the mother had described, until at last I learned that a short time before the vomiting came on the baby had eaten a small piece of banana, which the mother had given her. Here seemed to be a sufficient cause to account for the whole story, and an examination of the throat appeared to be a useless formality. Still, as the attention of the mother had been fixed upon this part of the body as the seat of the difficulty, I depressed the tongue and looked into the throat. Much to my surprise, I must confess, I saw a glistening object deep down in the pharynx. A second look brought it more clearly into view, and by the aid of a pair of forceps I removed, without difficulty, a small brass finger-ring which had, no doubt, been picked up by the child while creeping about the floor on the previous evening. It belonged to a sister of the patient, and the mother remembered that the children were playing with it on the night before. The ring was just large enough to fill that portion of the pharynx in which it was lodged, and was so placed that its axis corresponded pretty closely with the axis of the œsophagus, the anterior portion being caught and held in place by the epiglottis. The vomiting which took place was in all probability excited by ineffectual attempts to swallow or to reject it, and not by the presence of the piece of banana in the stomach, as I at first supposed; but the effort, although it may have changed the original position of the foreign body, had not sufficed to remove it. Deglutition was not much interfered with, for the child had swallowed water during the night, according to the mother's account, without apparent difficulty; but the muscular movements necessarily involved in nursing were no doubt productive of pain in the throat, and hence the refusal of the child to perform this function.

This case, simple as it is in itself, seems to me to point with more than ordinary directness to two important features. The first is the value of close observation, on the part of those who have the care of infants and little children, to detect the earliest indications of disease or derangement, and to seek advice for such as seem to require professional aid, instead of waiting to try the effect of domestic medicine, as so many people are prone to do. A delay for a few hours longer might have converted this case of simple mechanical obstruction into a dangerous and perhaps fatal malady. The second point is the importance, on the part of the physician, of never neglecting the investigation of any clew, no matter how slight, which may be of use in making a diagnosis. Often, it is true, such close attention will turn out to be a mere waste of time; but once in a while, as in this instance, a little trouble will amply repay one for any number of former unprofitable efforts.

Very truly yours,

W. R. FISHER.

HOBOKEN, N. J., November 11, 1876.

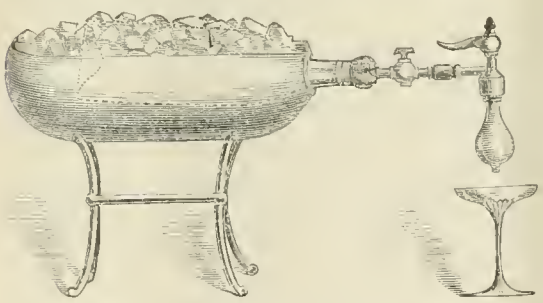
UNDERLYING A LIQUID IN A TUBE.—Dr. L. A. Frost, of Mechanicsburg, Ill., writes to us describing a convenient and ready method of underlying one fluid by another. He simply takes an ordinary test-tube, heats its centre over a spirit lamp, and draws out the bottom into a capillary tube, which in its turn is bent so as to be parallel with the original tube. The capillary tube is made as long as the other for obvious reasons, and its extremity expanded into a funnel. The fluid is poured into the larger tube, and the fluid intended to underlie it is poured into the funnel-shaped extremity of the capillary tube.

New Instruments.

WARKER'S IMPROVED SYPHON.

Mr. Thomas Warker, of this city, has devised an apparatus for the administration of sparkling wines, which promises to be of the greatest utility to physicians. It is well known, whenever wines charged with carbonic acid gas are prescribed for our patients, that after the bottle containing it has been opened and the first dose is taken, that most, if not all of the sparkle disappears, and, as far as any good to be obtained from the gas itself is concerned, it is virtually inert. The French contrivance of introducing a faucet with stop-cock through the cork, although apparently sound in theory, was found radically defective in practice. The wine was discharged with a spurt, and with considerable force, but contained little or no gas after the first glass was drawn. Mr. Warker, after a careful study of this phenomena, discovered that the object aimed at in this and all other similar contrivances—namely, the discharge of the wine under pressure—was the real cause of the loss of the gas in the glass. This theory, it seems to us, is abundantly substantiated by the ordinary method of obtaining the wine from the bottles. The operation of removing the cork is the signal for the discharge of the extra and supernatant pressure; the wine is then simply poured in the glass, and, if not allowed to stand too long, retains its accustomed sparkle. If, however, the entire contents of the bottle are not used within a reasonable time after being opened, we have also a loss of the carbonic acid which it contains. In this instance the gas escapes from the liquid because there is not sufficient pressure above to prevent it.

It is necessary to appreciate these facts in order to understand the principles upon which his contrivance is based. His objects are, first, to maintain the pressure in the bottle, or the ordinary syphon, as the case may be; and secondly, to discharge given quantities without subjecting them at the moment of their discharge to any pressure whatever.



The apparatus, as seen in the cut, consists of a bottle of champagne, the cork of which is perforated for the reception of a tube connected with an extra or receiving chamber. When a small quantity of wine is to be drawn, a direct communication is opened between the chamber and the bottle by means of a valve, and, when a sufficient quantity of the wine has escaped in the small receptacle, the valve is closed. The bottle and the extra chamber are then entirely independent of each other, and the pressure in each is relatively the same, and can be so maintained as long as desired. When the wine in the chamber is required, the opening of a compound valve relieves the pressure of the supernatant gas, and the wine thus relieved gently flows into the glass, containing even more gas than when poured from a freshly-opened bottle. As can easily be seen, this operation can be repeated with the same result until the bottle itself is exhausted. The practical application of this principle enables the physician to prescribe sparkling wines not only from syphons, but from the original bottles, and still preserve the sparkle until the entire contents are used. Aside from this, means are now afforded, by attaching this supplementary chamber to the nozzle of the ordinary syphon apparatus, of charging still wines, brandies, and even noxious draughts with gas, and administering them to our patients ad libitum. The question which naturally suggests itself in this connection is, why champagne and similar wines cannot be treated as the ordinary mineral waters, which are known to retain a certain amount of gas when discharged under pressure. The answer to this is, that Mr. Warker has found that, while mineral waters will so behave, the wines are governed by a different law, and hence the opposite result. Another advantage of this contrivance is the possibility which it affords of administering the different mineral waters charged with gas, and at different temperatures. Carlsbad, for instance, can be drunk at its natural elevated temperature, without suffering from the loss of its carbonic acid, which would be the case under other circumstances. Altogether, the scientific principle involved in this contrivance is as interesting to the physician as its practical application is destined to be beneficial to his patients.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 19 to November 25, 1876.

Gibson, J. R., Asst. Surgeon. Assigned to duty as chief medical officer of the Powder River Expedition. S. O. 156, Dept. of the Platte, Nov. 16, 1876.

Williams, J. W., Asst. Surgeon. Assigned to temporary duty with the troops at Washington Arsenal. S. O. 240, A. G. O., Nov. 22, 1876.

Patzki, J. H., Asst. Surgeon. Assigned to duty at Fort D. A. Russell, Wyoming T. S. O. 154, Dept. of the Platte, Nov. 14, 1876.

Dickson, J. M., Asst. Surgeon. Assigned to duty with 16th Inf. in New Orleans, La. S. O. 224, Dept. of the Gulf, Nov. 18, 1876.

Hoff, J. V. R., Asst. Surgeon. To accompany Co. G, 23d Inf., from Fort McPherson, Nebr., to Fort Fetterman, Wyoming T., and, on arrival, relieve Asst. Surgeon Gibson from his duties as Post Surgeon at that post. S. O. 156, C. S., Dept. of the Platte.

Barnett, R., Asst. Surgeon. Assigned to duty with battalion of 3d and 13th Infy. in New Orleans, La. S. O. 224, C. S., Dept. of the Gulf.

Crampton, L. W., Asst. Surgeon. Leave of absence extended one month. S. O. 132, Div. of the Missouri, Nov. 17, 1876.

Taylor, M. E., Asst. Surgeon. Assigned to duty with 3d and 13th Infy in New Orleans, La. S. O. 224, C. S., Dept. of the Gulf.

Rose, G. S., Asst. Surgeon. Died at Madison Barracks, Sackett's Harbor, N. Y., Nov. 20, 1876.

OFFICE THIEVES.—We are again reminded that office thieves are beginning to ply their trade.

Dr. C. M. of this city writes:

"SIR:—I think it my duty to drop you a line, as Editor of the MEDICAL RECORD, to ask you to warn the profession against a thief who is calling at the residences of the doctors just after their office-hours. He gave me a call on Saturday, and took a very fine bronze clock. He probably uses the same method with others as at my house. Observing me go out, he immediately called and told the girl he had just met me, and I had told him to wait—a plausible story. He is a tall, gentlemanly-looking person, black hair, black moustache and goatee. C. M."

NEW YORK, November 20, 1876.

The above letter calls attention to a comparatively new device for this class of sharpers. As the physician is more than ordinarily exposed to similar ones, it becomes him and his servants to be constantly on the alert. Under present circumstances it is a good rule to allow no stranger to enter an office during odd hours, merely to wait until the doctor may return. A desire to do so, on the part of a stranger, should at once arouse a suspicion. The wish on the part of the servant to be civil should not interfere with a request that the supposed patient shall call at the proper time, or leave his message. The neglect to do so has been the occasion of the loss of much valuable property, such as microscopes, surgical instruments, pictures, and clocks.

The most expert office thieves are generally females who, pretending to be very much disappointed at not finding the physician at home, and assuming to be much exhausted, ask to rest themselves for a while. If the physician happens to be at home they are ready to detail the history of some "womb trouble," and even submit to vaginal examination in order to save appearances. The suspicious circumstance of this manœuvre is the awkward discovery that they have forgotten their pocket-book. If these swindlers ever call a second time they will be careful to know beforehand that the physician is not at home.

It is impossible to detail the various tricks which are resorted to by these impostors. We have in mind the following amusing case, which may have a parallel in the experience of others. A female not long since called at our office during our absence, expressed great disappointment, but asked to wait a few moments for her carriage. There being no denial for such a reasonable request, the servant purposely busied himself around the office until the said carriage arrived. A day or two afterwards we learned from the proprietor of a livery stable in the neighborhood that a female answering the description of our would be patient had ordered the carriage in our name. The fact that she had visited many questionable places, aroused a suspicion in his mind which we speedily confirmed. Had the thief been allowed the usual facilities of appropriating any article of value within her reach, the coach would have been a very convenient means of transportation.

But, as we before remarked, this is only one of many methods of sharp practice to which physicians are liable; and as prevention in these cases is so much easier than cure, we believe that the motives of our correspondent in giving his late experience will be duly appreciated.

PRONUNCIATION OF THE NAMES OF GERMAN AUTHORS.—The following key to the pronunciation of the different authors' names in Ziemssen's Cyclopædia has been prepared for the purpose of promoting greater uniformity in the pronunciation of these names. It is scarcely possible to show, except *viva voce*, how the German *ue*, or *ch* (or *ig*) should be pronounced; and, even if the proper pronunciation could be shown, probably very few physicians would ever attempt to employ it in ordinary conversation. Hence, the sound of *u* in *ruler* has been substituted for that of the German *ue*, and the sound of *k* for that of *ch*. As such names as Wagner, Thomas, Weber, etc., have already been acclimatized in our language, it is doubtful whether it would not rather add to the confusion to pronounce them as Vargner, Toemar, Vayber, etc. Still, for the sake of completeness, they have been included in the following list. The English pronunciation of the letters *st* is both easier to use and pleasanter to hear than the German *sht*; the latter pronunciation has, therefore, been omitted in the following list. Finally, no attempt has been made to reproduce the soft sound (in French) of *j* before *o*, as in Jolly.

FRENCH INTERNES.—The appointment of "interne" of French hospitals is held for four years, during which time transfers are made from one institution to the other, affording an extensive experience in the general and special parts of the profession. The custom in New York hospitals is to limit these appointments to eighteen months each.

STATE BOARDS OF HEALTH.—Eleven States now have State Boards of Health. Massachusetts led the way in 1869. She was followed in 1870 by Louisiana and California; in 1872 by Virginia; in 1873 by Minnesota and Michigan; in 1874 by Maryland; in 1875 by Georgia and Alabama; and in 1876 by Wisconsin and Colorado. When the State Board of Health was organized in Michigan, Dr. Hitchcock said that the loss to the people of that State caused by preventable sickness was more than $2,000,000 per annum. "It is our office, then," said he, "to make the labors of this Board popular with, because useful to, the people of the State. Here," he continued, "is the work for this Board to do; to educate the people in respect to the nature and causation of diseases, and the means for their prevention; to suggest appropriate legislation for compelling, when necessary, the use of these means; and to present arguments for such education and legislation, fortified and made cogent by facts, well authenticated cases of disease and death directly traceable to ignorance, neglect, or disobedience of the laws of hygiene; and to make it possible by this work that many, if not all, the lives and much of the treasure now needlessly lost to the State may be saved." Imbued with the same spirit, the members of the Wisconsin Board recently met at Madison and organized for labor.—*Sanitarian.*

A NEW FORM OF ASPIRATOR.—The London *Lancet* (Nov. 4) calls attention to a new form of aspirator devised by Dr. Gritti, of Milan: "The instrument consists simply of an ordinary double-ended india-rubber syringe, resembling the common Higginsou's syringe, to the tubes of which are affixed nozzles adapted to fit into the aspirating needles or trocar. Before using the instrument for aspiration the ball and tubes are to be completely filled with water, and after introduction of the needle into the chest (if in a case of pleurisy) the inlet tube is fitted on to the needle, and the instrument worked in the ordinary manner until the desired amount of fluid has been evacuated. If it be needful to inject any disinfectant or other solution after removal of the fluid, this is readily accomplished by reversing the apparatus and fitting the outlet tube to the canula or needle. If the capacity of the ball be previously ascertained, the number of strokes needed to inject any given quantity affords a ready method of measuring how much is thrown in. The apparatus appears to us to possess many advantages, provided always that the suction power of the syringe is sufficiently great. It affords a method of removing the fluid gradually, and with an even pressure throughout the operation; it is portable, cheap, and readily replaced, and it does away with the necessity for a complicated apparatus, the stopcocks of which are a puzzle to the uninitiated, and which is a source of alarm to the patient. Added to this is the advantage of its ready reversal. Should it be found a success, it will be another proof of the simplicity of useful inventions."

INFLUENCE OF PINE FORESTS ON THE RAINFALL.—Some interesting observations have lately been made by M. Fautral on the influence of pine forests on the quantity of rain received by a country, the hygrometric state of the air, and the state of the ground. It is proved that pines have the property of condensing vapor, and that in a much higher degree than leafy woods. Thus the quantity of rain which fell over a pine forest during fourteen months was 840.70 mm., as against 757.75 mm., on the open ground three hundred metres off, showing a difference in favor of the forest of more than 10 per cent. of the latter quantity. In the case of oaks and witch-elms the difference was only 5 per cent. The mean saturation of the air above the forest was ten-hundredths more than at the other station (63 against 53). The quantity of rain received by the forest ground was 471 mm., while 369 mm. was interrupted by the trees—*i.e.*, 0.43 of the water precipitated. Now, though the open (sandy) ground received 757 mm., there is reason to believe that the forest ground really conserves more water. These data show what services may be rendered by pine forests on burning, sandy, or chalky plains, which the want of water renders unproductive. Such forests, too, are a powerful remedy against inundation.—*Medical Press and Circular.*

RETURN OF THE SECRETION OF MILK.—It is well known to foreigners resident in China, that the Chinese women who have borne children are able to excite anew the secretion of milk years after the last child had been weaned. Dr. Muller reports two cases of this curious phenomenon that were observed by him. A woman, aged 30 years, whose breasts were completely retracted, and had been inactive for six years, took a child six months old, which she placed frequently to her breasts, confining herself at the same time to a special diet. Ten days later the milk began to be secreted, and after six weeks Dr. Muller found the breasts firm and well developed, and pressure caused a stream of milk to flow out. The menses ceased while this lactation continued. The general health was very good. By similar means the secretion of milk was re-established in a woman forty years of age, whose youngest child was nine years old, and had not been nursed for six years. In this case menstruation did not stop, but it became less abundant. In a third case the attempt to re-establish the secretion of milk excited such disturbances of the general health, that it had to be discontinued. In the two first cases the milk was carefully examined and found to be normal; its spec. grav. was 1030.

AN IRON CALCULUS.—A man in Paris recently passed a urethral calculus the size of a hazel-nut. Its passage was attended by severe nephritic colics. M. Cazeneuve found, on examination, that it was entirely composed of almost pure peroxide of iron.

Original Lectures.

CLINICAL LECTURES ON ACUTE DIARRHŒA.

DELIVERED IN BELLEVUE HOSPITAL,

By W. H. THOMSON, M.D.,

PROF. OF MATERIA MEDICA, MEDICAL DEPARTMENT UNIVERSITY OF NEW YORK.

LECTURE II.

We have dwelt at such length upon the causation and the treatment of infantile diarrhœa, because the principles then enunciated are equally applicable to the commoner forms of acute diarrhœa in adults. In brief, we might say that the majority of cases of summer diarrhœa are caused by a fermentation of the intestinal contents due simply to a deficiency of the normal digestive secretions; and therefore, that the first indication is to remove the fermented matters, and then to re-establish the flow of the natural juices. This is a different view from that usually entertained by our patients, viz., that we should give them something which will act as an immediate check to the flux; and hence a beginner is often unconsciously influenced by this natural impression of theirs towards administering opiate and astringent mixtures without delay. But nothing will check a diarrhœa so soon or so well as a single day's flow of natural secretions. Could we artificially prepare an exact counterpart of them both in their antiseptic and their solvent properties, I doubt not that we would find such a mixture the best astringent for diarrhœa possible. The question for us to ask, therefore, is, what secretions are probably the ones most deficient or perverted in this affection, and how best can we restore them.

In the first place, it is not likely that the gastric juice is as lacking in a case of acute diarrhœa in an adult as it is in infantile diarrhœa. In dysentery, on the other hand, there are reasons to suspect a notable deficiency of gastric secretion, as I will explain presently. But in ordinary summer diarrhœa the symptoms of gastric dyspepsia are not usually very marked, at least not at first, and not until the system is beginning to feel quite sensibly the effects of the disorder. It is not uncommon for the patients to have a good appetite for several days after the diarrhœa commences, and to feel uncomfortable only when the stage of gastric digestion has been passed for some time. Diarrhœa also, properly speaking, does not implicate the large intestine nor depend upon an abnormal state of its secretions, for when indications of dysentery set in, we have a train of symptoms which plainly contrast with those of diarrhœa. A patient with dysentery is disturbed by food almost immediately after it has entered the stomach, so that in many cases nothing is so calculated to excite a desire for stool as the partaking of an ordinary meal. In dysentery, therefore, whether acute or chronic, it is very common to note the unaltered smell of the components of a dinner. A patient of mine once said that he could detect in a dysenteric discharge the odor of a small piece of beefsteak which he had eaten but a short time before. It is on this account that you will probably never meet with such specimens of pure starvation as in some children with dysentery, who will void the milk they take almost immediately after it has been swallowed; but such an occurrence is not to be expected in a case of true diarrhœa, no matter how profuse or frequent the discharges may be.

The explanation of this difference between these allied disorders is to be found in the nervous mechanism of the alimentary canal. There appears to be in health a mutual understanding, so to speak, between the sensory nerves of the stomach and those of the rectum. The natural time for an evacuation from the rectum is directly after breakfast, that is, when the stomach receives food after its longest period of rest. Irritation of the rectum, on the other hand, seems by this alliance to be reflected upon the pylorus to so paralyze its sphincter-like action, that the food is not delayed long enough in the stomach to be acted upon, and hence it is then equally unfit for intestinal digestion, and is hurried on to be voided as soon as possible. I may remark in passing, that the consideration of such facts in the nervous connections of the digestive canal as this feature of dysentery illustrates, has appeared to me to afford a hint of the cause of the abnormal appetite which characterizes certain cases of nervous disease, as in epilepsy, insanity, etc. The sense of hunger has its seat mainly in the gastric nerves. In these cases I allude to, the nervous disease is always accompanied by a hurry in swallowing. The patients bolt or gulp their food and drink, and it seems reasonable to infer, that along with intestinal paralysis and constipation in them, there is still the same hurry in the action of the stomach, which empties itself into the sluggish intestine before the hunger is appeased, as it would be if the food remained long enough in contact with the gastric walls.

But to return. The commonest period both for the onset of diarrhœa and for its most abundant discharge afterwards, is early in the morning, indicating an accumulation above the cæcum during the rest of sleep. Dysentery, on the other hand, is most relieved by rest, and most excited by movement of the body, and also, as we have just stated, by a meal. Diarrhœa, therefore, is generally due to a disorder in the secretions which empty into the small intestine, and of these we may be sure that the duodenal secretions are the most frequently affected. Among many indications of this in the acute forms, we may frequently note that both preceding and accompanying its development we commonly find a muddiness of the conjunctivæ, and yellowish streaks about the mouth and a muscular languor, with slight aches around the shoulder and down the back, which are rightly diagnosed by the patients themselves as signs of "biliousness." Now there are a great many causes operating during the hot months, which may with much probability be regarded as effective in changing the character of the secretions which empty into the duodenum. All vegetable acids, for example, when taken in excess, have a greater tendency to neutralize the alkalinity of these secretions than we find in the case of the mineral acids. I doubt, for instance, whether there is anything so certain to cause an obstinate looseness of the bowels as a persistent use of lemonade. The acids of fruits, when in excess, I believe, therefore, are quite as "bilious" as fats can be, and quite as frequent causes of diarrhœa as their presumably indigestible pulp. Moreover, the biliary and the pancreatic secretions, taken together, are among the densest secretions of the body, and a too free ingestion of water, even when pure, may dilute them too much for their proper action. But water in warm weather is often anything but pure, and how much of perversion is caused by its condition it is difficult to say. If, as is believed by many, the malarial poison is introduced as frequently by what we drink as by what we breathe,

we may have another potent cause for the duodenal secretions becoming affected by our yielding too freely to the demands of thirst on a summer's day. But we need not multiply such surmises as to the genesis of these perversions, for all we wish to illustrate by them is the probability that an effort to increase the alkalinity of the intestinal fluids, and along with this to administer medicines containing both resinous and antiseptic ingredients, would seem to offer the most rational prospect of relieving the disorder.

Now among all our remedies, there is not one which appears to increase the flow of the natural secretions of the bowels like rhubarb; for while the cathartic oils act mainly by producing a catarrhal condition of the mucous membrane, and the irritant resins by an operation similar to the irritation of the intestinal fermentation itself, and the salines by preventing the water in the intestine from being absorbed, rhubarb causes the dejecta to present more normal characters than any in the list. It is often pronounced an astringent on account of the rheotannic acid which it contains. But tannic acid itself in anything like the small doses which would correspond to the astringent ingredient in rhubarb, would show but little control over a flux, and hence the constipation which often results after a dose of rhubarb ought to be explained otherwise. The normal secretions restored by the operation of this remedy, are themselves the causes of the stoppage of the flux, and the constipation which follows is nothing more than a natural result of the previous over-stimulation of the intestinal secretions. The common addition of alkalies, like soda and magnesia, is justified by the considerations already advanced of the necessity for alkalinity in the intestinal juices, while the still further addition of spices or aromatics supplies the indication for antiseptics. The oils contained in spices, like cloves, ginger, cinnamon, etc., are close allies chemically with phenic or carbolic acid, and hence their preservative powers, which are made use of in pickling, etc. But it is not so generally known that camphor, oil of peppermint, and notably oil of winter-green (Gaulotheria Procumbens, not the Pipsissewa), are equally members of the chemical series to which carbolic acid belongs. From oil of winter-green also, salicylic acid can be derived even more readily than from salicin itself; while it illustrates the relationship which I have just mentioned between these various vegetable products, to know that salicylic acid is now chiefly made from phenic acid itself.

In recommending these old remedies, therefore, whose value experience has shown for so long, I have aimed to explain why they are beneficial, in order to prevent you from giving them up too soon under the temptation to resort to opiates and astringents. You rarely relieve an acute diarrhœa by these last, unless it be already nearly cured by natural means; but I have seen many instances of chronic diarrhœa which had become quite difficult to arrest, from what I believed to be a too early and persistent use of opiate and astringent mixtures. Opium is a very effective agent for suspending digestive secretions, as is often disastrously shown when it is administered to check the cough of phthisis, and hence I give it in diarrhœa only after the failure of the first remedies recommended, and then generally in combination with them or with other adjuvants to be mentioned presently. The first prescription for an adult, therefore, would be something like this: ℞ Magnes. sulph. ʒ vi.; Syr. rhei arom. ℥ iiss.; Ol. gaulotheriæ gtts. x.; Aq. menthæ ad ℥ vi. M. S.—Tablespoon every three hours.

Should the irritation, however, produced by the fermentation be so great as to cause a condition of persistent intestinal catarrh, we may then have recourse to astringents; but if so, I must prefer the mineral acids to the vegetable astringents, and would alternate with the above prescription the following modification of Hope's Mixture: ℞ Acidi nitr. dil. ʒ iv.; Tr. camphoræ, Tr. opii, āā ʒ iss.; Syr. zingiberis, ℥ i.; Aq. cinnamomi ad ℥ iv. M. S.—Two teaspoons in a little water. It is only when the intestinal inflammation reaches such a degree that fever is developing, that you should have recourse to more active astringent measures. Should such a condition arise, the indication for the administration of the acetate of lead is plainest, because it is the only astringent we possess which is also a local sedative to inflammation, while the other mineral, and still more the vegetable, astringents are local irritants.

Original Communications.

LISTER'S ANTISEPTIC METHOD IN OVARIOTOMY.

By J. MARION SIMS, M.D.,

NEW YORK.

Professor Lister's late visit to this country seems to have given a new impulse to antiseptic surgery. Van Buren has adopted it with success, and is lecturing on it to his class at Bellevue with great enthusiasm. Stephen Smith has also adopted it with the same success, and is teaching it most earnestly to his class at the University, and other surgeons must take is up. I have often wondered why it had not been used in ovariotomy. Lister told me it had not been done in Great Britain. He advocated it strongly, but Spencer Wells and Keith have had such wonderful success in their operations, that they did not feel justified in trying any new method.

I would have used it long ago if I could have found a convenient and ample spray-producer.

A fortnight ago I heard that Dr. Sass had perfected an apparatus, and had tested it in operations by Van Buren, Stephen Smith, and others. I saw Dr. Sass, and he kindly consented to bring his apparatus, and apply the carbolic spray for me in a case of ovariotomy.

The patient, forty-seven years of age, noticed a tumor the size of an orange in the right iliac region last April. She consulted her family physician, who pronounced it an ovarian tumor. In June she consulted Dr. Thomas, who wisely told her the time had not arrived for an operation. On the 20th July she went to Philadelphia to see Dr. Atlee, who gave her the same good advice. I saw her on the 20th September. I have never seen any one so anxious for an operation. I dissuaded her from it, advising her to return home, and wait at least till next spring. I told her the tumor did not weigh more than ten pounds, and that an operation was not justifiable till she vomited her food, and began to emaciate. I saw her a month later. She declared she had not the strength to make the journey home, and that she threw up every time she took food. I still refused to operate. She wrote to Dr. Atlee, and he replied on the 6th November: "I can scarcely think a tumor so small can affect your general health so seriously. But if your emaciation and debility are the result of the presence of the tumor, then by all means it should be

removed." I believe her vomiting and consequent emaciation were mainly the result of mental and moral causes. Whatever the cause, her declining strength and a recent fugitive attack of peritonitis warned me not to procrastinate the operation any longer.

The operation was done on Thursday, the 23d November last. I am particular in fixing the date, because I believe it inaugurates a new departure in ovariotomy.

Dr. Sass directed the spray, which covered the seat of operation with a delicate carbolic mist. The hands, sponges, and instruments were all dipped in carbolic water. The operation and dressing lasted forty minutes, the spray being kept up all the time. It could have been continued two hours, if necessary. There were no adhesions. The peritoneal cavity contained six or eight ounces of a reddish serum. The peritoneal membrane was everywhere deeply congested. This fact explains the presence of reddish serum, and the previous attack of peritonitis.

The pedicle was very short, and at least three inches broad. It was tied in three sections with strong twine, and drawn out and fixed in the lower angle of the wound, clamp-fashion.

The external incision was closed by sutures, and a carbolized dressing applied.

The pulse never rose above 90, nor the temperature over 101.

Convalescence was fully assured in forty-eight hours, and the patient is now quite well. The tumor was polycystic, on right side, and weighed fifteen pounds.

I hasten to lay this case before the profession merely to urge the adoption of Lister's antiseptic method in ovariotomy, which, I am sure, will prove as valuable in this operation as it has in general surgery.

Dr. Sass's apparatus answered its purpose admirably, and I think he has rendered us a great service in bringing it before the profession at this time.

OPIUM INEBRIETY.

By J. B. MATTISON, M.D.,

BROOKLYN, N. Y.

(Read before the Medical Society of the Co. of Kings.)

In accepting the invitation kindly tendered me to prepare a paper for presentation this evening, I have done so with the most appreciative sense of my inability to proffer more than an outline of a subject great and growing in its importance, and which demands of him who would do it full justice time in excess and talent in advance of that I have bestowed upon it.

The topic to which I am desirous of directing your attention, and which I trust I shall be able to invest with a larger share of interest than you have hitherto, perhaps, accorded it, is Opium Inebriety: its Pathology, Etiology, Prognosis, and Treatment.

I am well aware that, in so doing, I am instituting a new departure from the ordinary line of investigation concerning a most important factor in the weal of a common humanity; but if I can succeed in impressing upon you the fact that in opium we possess an agent potent for *evil* as well as good, and whose power in this regard has failed of receiving from our great body professional the attention it so deservedly demands, it may be that, in time to come, being forewarned you will be forearmed, and able to avert a danger which is far from fanciful, but has in it, when fully established, that which leads down to the darkness of moral and physical degradation or death.

An assertion that the consumption of opium in this country during the past quarter of a century has increased to an extent utterly unwarranted by its need as a therapeutic measure pure and simple, will, I presume, pass unchallenged. No one will deny that a marked change has occurred in the practice of medicine so far as the employment of this drug is concerned; but that, alone, is entirely inadequate to explain the inordinate demand at present existing.

Casting about for an explanation, we find there has been established among us a diseased condition, not, it is true, enumerated in our nosology, but which has, nevertheless, as asserted by high authority, "attained stupendous dimensions, lying ambushed beneath the foundations of health and happiness," and which presents, in many instances, a symptomatology as marked and specific as that of the better-known ills to which our flesh is heir.

After a time more or less prolonged, according to varying circumstances, an individual who has been employing opium, be the cause thereof what it may, finds himself the subject of sundry uncomfortable sensations for which he is unable satisfactorily to account; but in many cases ignorant as to their real nature, or supposing them to be some new manifestations of the disorder for which the drug was administered, no suspicion is aroused, its use continued, and this order of affairs repeated, eventually engenders a condition in which the demand for the stimulant is imperative, and the pitiable sufferer becomes the victim of an appetite that will not be denied; a craving that is, in almost the entirety of cases, absolutely irresistible.

Or, it may be, a patient well aware of the danger attending a protracted employment, fails of its full appreciation until some peculiar circumstance calls attention thereto, and then, if not too long delayed, a tremendous effort, costing distress of mind and body, may succeed in casting off the incubus; but in too many instances the power to will has become so prostrated that it is unable to reassert itself, and the hapless individual is given over to a servitude most deplorable.

Again, as more often happens, patients continue its use without the slightest idea of this danger supervening, being unaware of its ensnaring property and unwarned by their medical attendant; and when relieved, as they suppose, of a necessity for its continuance, and an attempt is made at abandonment, are horrified at finding it impossible so to do, and unless helping hands come to the rescue, almost invariably find themselves relapsing into their former condition.

Then, too, are those who, with an inordinate desire for stimulants of some sort, have recourse to opium for various reasons, as one demand or another for its use may be uppermost. The man of letters finds his eagerness in the pursuit of knowledge quickened and enhanced thereby. The orator discovers his flights of fancy and bursts of eloquence more easily attainable with than without it. Authors, under its influence, find themselves in possession of a larger storehouse from which to draw the material for their literary productions. The men and women of society discover the charm of their accomplishments, be the sphere of their adornments what it may, largely increased by its wonderful power; and the votaries of pleasure, exhausted by the round of their dissipating indulgence, resort to it to rekindle, in their well-nigh effete frames,

the fire that has burned so low and threatens to go out altogether.

Sooner or later, various functions become disordered. One of the earliest and most constant is an obstinate torpor of the intestinal tract, diarrhœa occasionally alternating; the appetite becomes impaired, and indigestion holds high carnival; the skin grows dry and harsh, and its natural color gives place to a tinge yellowish or bronzed; the eye loses its accustomed brilliancy and assumes a dull, lustreless look; flashes of heat and cold succeed each other; cramp-like pains rack the body; sleep vanishes, or is troubled, dreamful and altogether unsatisfying; the face becomes pinched and haggard; emaciation ensues; the strength declines, and the wretched unfortunate becomes, indeed, a mere physical wreck of his former self. Mentally, the condition is deplorable. Tossed about by conflicting emotions, preyed upon by distressing doubts and fears abiding, conscious of his thraldom and the impotency of his efforts at emancipation, the abject slave to this galling bondage goes through life surrounded by a darkness seemingly impenetrable and, at times, down "into the very depths of despondency and gloom." The strong becomes weak, the brave a coward, and all the nobler attributes of a vigorous manhood are swamped in the overwhelming rush of this imperious appetite.

Gentlemen, this is no fancy picture. I have seen a man whose courage would have carried him to the cannon's mouth, and whose eloquence has thrilled the councils of his State and the nation, so powerless in the grasp of this monster, that his helplessness was indeed pitiable to see. I have known a patient declare he would sooner endure for days the exquisite pain of a mortal neurotic lesion, than be enshrouded a few hours in the gloom that pressed itself down upon him as a result of his thraldom to opium. Those of you who have read the pages of Coleridge, will remember the graphic recital of suffering as a sequence of his slavery to this most tyrannical of masters. This, in fact, constitutes one of the most painful features connected with an enslavement to opium, and in many cases, doubtless, far transcends the mere physical distress. As has been well remarked, "but few know the terrors of those who are thus diseased. But few can comprehend the torment of a sensitive moral nature that by reason of its very sensitiveness has yielded to the bondage of appetite. But few apprehend the physical demand for composure and even oblivion that haunts a restless, nerve-worn nature, and many more should be willing to shield a brother's infirmity with the same covering of charity which they would themselves desire under a similar invincible pressure."

The description above given, applies of course only to cases where from peculiarity of constitution, hereditary or acquired, or from the extent and duration of the disease, the system has undergone a well-marked transformation. In the earlier stages the effects may be quite satisfactory, as has been observed by one who speaks whereof he knows: "The victim takes his first dose and feels exalted, serene, confident. His intellectual faculties are so adjusted that he needs but call, and they obey; discipline and order reign. His load of care, the tedium of life, his aches and pains, and 'the spurns that patient merit of the unworthy takes,' are all lifted from his shoulders . . . . The beams pour in, the clouds disperse, and all is bright as noon-day. But this calm is only that which precedes the storm. The nerves, that system of exquisite mechanism in man, have been interfered with and abused. There has been an unnatural strain; the harmony of tension has been disturbed and deranged; and now, instead of discipline and equanimity, cruel disorder and distraction rule the hour."

The time required for bringing about this latter result admits of wide variation. I have notes of an instance in which the inebriate plodded along nearly seven years seemingly contented, save in unimportant particulars, so long as there was no interference with his accustomed intoxicant. Recently I have been made acquainted with the case of a gentleman who has been an habituate for a still longer period; but owing to an originally strong constitution, it is only now that he feels impelled, from the encroachments the disease has begun to make upon him, to seek relief.

Individual instances vary largely regarding habitual consumption. The maximum daily quantity in cases under personal care was twenty grains of morphia subcutaneously; the minimum a fraction less than $\frac{1}{10}$ that amount. The extent of habituation, either as to time or quantity, affords no criterion of the effect produced, being sometimes strikingly disproportionate, and in the instances mentioned the results were much less disastrous in the larger consumer, and this too despite the fact that his addiction was more than triple in duration that of the other. The literature of this part of the subject presents some examples so extraordinary as to seem almost beyond belief; and among them the most notable in all respects, of which I have knowledge, occurred under the observation of Dr. John Van Bibber of Baltimore, and may be found in full in the Archives of Neurology for May, 1875. This gentleman reached a maximum of 60 to 80 grs. morphia, hypodermically, per diem, with the addition of from one to three pints of whiskey and eight or ten strong cigars. Under treatment he improved, but eventually succumbed to the triple pressure of his alcohol, opium, and tobacco. Opium inebriety presents itself in a twofold aspect, that of a vice and of a disease; and in cases primarily the former, it sooner or later eventuates in the latter. As a vice, those instances—a marked minority I think—in which the initial taking is a reprehensible desire for its stimulating properties, apart from any condition demanding its pain-relieving power—a mere wish for its pleasures, with or without the knowledge that its pains will prove to be greater than any delights it may furnish if its use be continued.

As a disease, those cases where its primal employment is legitimate, having the sanction of professional authority, and in which its use is persisted in until the morbid condition becomes thoroughly established. Just when the line of demarcation will be reached cannot with positiveness be predicted. Various modifying circumstances may exist in individual instances tending to prolong the time during which volition exerts a controlling power; but its reign is of necessity limited, and then opium inebriety as a vice is supplanted by opium inebriety as a disease. The shortest time which I have known required to establish this latter condition was three weeks, at the expiration of which, although the disease originally demanding it was subdued, the opium was not, and the gentleman remained an inebriate for many months, the final result being favorable.

Opium inebriety demands a congenial soil for its development. The nervous temperament furnishes a fertile field. We are essentially a people of this type, the most so, Dr. Beard asserts, on the globe. Neurotic diseases are rife among us, increasing rather than otherwise; and to their growing frequency and the consequent freedom, amounting at times, I feel bound to say, to recklessness with which the anodyne properties of this drug are invoked for the mitigation

of pain, is to be ascribed in most measure the alarming proportions to which this disease has attained among us.

The majority of individuals liable to become inebriates possess a constitution so in harmony with its seductive properties, that the exhibition of opium for more than a limited time exposes them to the risk of inebriety. Probably not a few among you are cognizant of those on whom it exercises this fascinating influence, and whose safety would be seriously imperilled by a somewhat prolonged administration. The limits of this paper preclude an analysis of this favoring diathesis, and it will suffice to say that the leading factor thereof is a strongly marked *hereditary* tendency to debility of the nervous system, either special or general, as evidenced by an ancestral mortuary record in which neurotic lesions present a prominent predominance. I do not wish to be understood as saying that the one is, of necessity, the corollary of the other; but I believe the exceptions not numerous; and if the proposition in the main be correct, the care demanded in determining the status of an individual from the stand-point of hereditary tendency prior to a protracted employment is too obvious to call for comment.

Touching thus superficially on some of the more salient points connected with this disease, we pass to consider the question of cause, which, in its practical relation to ourselves, as physicians, I take to be the most important part of the subject; for, if what is deemed the leading agent in its origin be correct, then opium inebriety becomes in large degree a disease preventable, and as such assuredly deserves our consideration.

Relegating to abler authority the great question of the etiology of inebriety in general, and restricting attention to this special type, What is the initial cause of its development? Do men take opium from choice merely for its pleasures; or is it that, once ordered on professional authority for some ill, fancied or real, and continued a time indefinite, the patient, never dreaming of the danger he is courting, finds himself, when therapeutic indications for its use have been fulfilled, a victim? Touching this, observation varies; though the preponderance of testimony favors the cause last mentioned. A recent writer holds to the opposite view, his language being: "In accordance with the best information I have been able to gather, the largest number of opium eaters contract the habit from choice, merely for its pleasures." Prominent among those well qualified to pass judgment on this question is Dr. Parrish, who reaches a directly contrary conclusion: "Men take it not for social enjoyment, but for a physical necessity." Another authority in this country remarks: "For the primary induction of the habit, the stated physician is so commonly responsible, that the *onus probandi* in exculpation rests upon him by all fair presumption." A late German writer says: "The original causes of this diseased condition, and of its extension, are the doctors themselves, who have accustomed patients to resort to the use of injections for the relief of painful affections of more or less short duration." Further corroborative evidence comes from another foreign source, in which the writer, after noting three cases of this disease coming under his care, all having their inception in an opiate prescription, remarks: "This leads me to say that I think there are many cases of chronic disease, or disease in which sleeplessness is a prominent symptom, in which opium is frequently prescribed without any thought of this danger supervening, and which has led me to believe and practice that it is advisable not to give opium continuously for any length of time in these cases, unless in painful and incurable diseases, as cancer, etc., especially if the patient is of a nervous temperament. There is no doubt that pain or sleeplessness would more frequently have to be endured, but other remedies might be substituted which would, in part, though not entirely, take its place. And, if we consider that it would save some, more perhaps than many are aware of, from contracting such a habit, I think that at least it would be advisable to consider this danger and bear it in mind when we are called upon to treat such cases and believe opium to be indicated; a danger which most readers well know, from their own experience, not to be a fanciful one." After referring to the strictures sometimes passed regarding the medicinal employment of alcoholic stimulants, he continues: "But it is otherwise with those whom I have mentioned, who have not known the potency of this drug, at least personally, until it was professionally administered, and who, in all likelihood, would not have known it unless so ordered. And this is generally the rule, I think, that the majority of habitual opium-eaters have, in the first instance, acquired the taste for it after having been ordered it by a medical man; and in view of this danger, I venture to say that this ought to be borne in mind when we administer opium in these cases, lest we might be the innocent cause of setting the spark to the fire that may only be extinguished with life." Speaking from personal observation, my testimony militates a statement as to the voluntary induction of this direful degradation.

If this be true, what is the great lesson to be learned on this most important subject? Simply this, that the necessity for caution in the prescribing of opiates rises to that of a *duty*, in view of the fact that much the larger number of victims to this baneful bondage become such through the unintentional ministrations of their medical attendants.

Respecting the prognosis of this affection, various circumstances may exist in individual cases affecting the probability of a successful termination. If the inebriety be the *only* disease, no complication existing, the prospect, of course, is heightened, though I am somewhat sceptical regarding the assertion of a recent writer, himself a ten years' sufferer, but finally relieved, that every case of opium inebriation not complicated by organic derangement, admits of cure. The extent of habituation as to *duration* is of greater import in determining the likeliness of a favorable eventuation than the mere daily quantum consumed. The longer the addiction the less favorable the prognosis, though to this there are, I believe, some striking exceptions. Much, too, depends on the patient's condition at the time restorative measures are adopted. If the general health be not very greatly impaired, and if, in addition, can be aroused an earnest purpose on the part of the sufferer to co-operate cordially with whatever mode of medication is adopted, an unyielding resolve to persevere in treatment, never doubting the issue, a strong point is gained and the prospect of recovery very greatly enhanced. Dr. Lewenstein says that scarcely twenty-five per cent. recover. Dr. Parrish remarks: "Of the cases miscellaneously presenting, one-third are curable if conducted under institutional régime." Dr. Day gives similar testimony. Dr. Calkins writes: "In a certain percentage, not yet defined, of cases curable, but under this primary and essential condition, that the patient is, for the time being, morally, if not physically, subject to the supervision and guidance of his physician." Dr. Van Deusen observes: "Our experience has satisfied us that a large share of the cases deemed as having got beyond the reach of

medical aid can be successfully conducted; but then on this one condition only, that the physician shall have the entire and exclusive control. As for efforts at reformation voluntarily undertaken and successfully carried through, the cases are so extremely exceptional as never to be counted on; but when a course of treatment has been submitted to and faithfully prosecuted to the end, the result is directly the other way." My personal experience in the management of this disease is entirely substantiative of this latter statement.

Regarding treatment, a wide diversity of opinion exists as to the propriety of a sudden or gradual withdrawal of the habitual intoxicant. There are those eminent in the fraternity who favor the former practice. And in one case under my care, a prominent surgical authority advised the man's incarceration, and the morphia shut off at once and forever. Sooner than submit, the patient declared to me he would have attempted self-destruction. Howe, in "Emergencies," asserts that "tapering off will not result in cure." This statement is a very mistaken one, as the successful experience of more than one practitioner can well attest. Dr. Lewenstein states: "This is best effected suddenly, rather than progressively, the economy supporting an energetic procedure of this kind more easily than one more gradually conducted." Dr. L.'s cases may have been such as to warrant him in this assertion; but as applying to opium intoxicants in general, I am doubtful.

In large inebriate asylums immediate abandonment is urged as being more active and prompt; but it must be remembered in this connection that these institutions are able to impose physical restraint, without which, in well-marked cases, it is well-nigh impossible to secure success if this plan, which may well be called heroic, be adopted. Advocates of this method argue that opium is a poison, and as such should be at once discarded, and that its votaries, so long as they are allowed to experience its exhilarating effects, clamor for its continuance. The logic of the first proposition is open to question; and as to the latter, it is a fact that, so far from actually craving the drug, opium habituates entertain a feeling distinctly the reverse. Instead of a longing, a loathing; a disgust, rather than a desire; for, be it remembered, the morbid appetite is the result of the diseased condition, and as such strictly involuntary—outside the will's domain. Absence of the accustomed supply gives rise to great mental and physical discomfort, almost invariably precipitating the patient into a renewal; but this proceeds not from any wish for its mere exhilaration, for, in many instances, this is lost altogether; but from the reason that the will is weak, and when the crucial time arrives gives way entirely; so that, to use the striking language of a sufferer, "the drug-damned victim resumes the hell-invented curse."

Opposed to this treatment is what may be termed the reductionary mode of management, which consists of an immediate diminution to the point of toleration, and thenceforward its decrease in quantity, more or less minute, according to the degree of suffering attending its withdrawal; meanwhile surrounding the patient by circumstances hygienically favorable, and employing such direct medication as will best tend to sustain and strengthen the shattered nervous system and make amends for the abstraction of the adventitious support. The leading advocate of this method in this country says: "Our experience in the treatment of opium cases has satisfied us that it is neither wise nor humane to deprive the sufferer of his usual allowance all at once, but rather to grant a certain indulgence. Our practice is, in the general, to curtail by two-thirds, and upon the remainder to make reductions by inconsiderable fractional differences." A similar plan is, I believe, pursued in the public institution under charge of members of this Society. It has, too, operated successfully among cases in private practice, and is, in my judgment, best adapted to a majority of instances of the disease.

The reasons advanced in its favor are, that by it is avoided the shock which would of necessity ensue on a peremptory setting aside of the entire supply. Again, patients presenting themselves for treatment are often so reduced in their general condition as to require restorative measures to recuperate to a point at which they will be better able to bear the pressure when the time of trial comes. Then, too, by this plan can sooner be secured the confidence of the patient—a factor of no trivial significance, since by assuring him that the treatment will be as painless as it can well be made, his courage, all too drooping, more likely can be revived, and he induced to lend his co-operation with whatever measures may be deemed advisable. And by thus securing the trust, an excellent foundation is laid for the moral part of the treatment, which must most certainly react with favor on the physical.

At first sight, an immediate reduction of one-half or two-thirds seems almost dangerously rapid; but the fact is, opium inebriates frequently become possessed of the idea that their supply must be increased, so that at length they are consuming a quantity entirely in excess of what is actually required, and a very decided decrease occasions but little inconvenience. I remember an instance in which the descent was made from five grains hypodermically, daily, to two-thirds of a grain, before any material discomfort was experienced.

In the front rank of therapeutical measures is to be placed what may be termed a stout diet—an abundance of richly nutritious food, of such character and variety as shall seem best adapted to repair the waste effected. As an admirable adjunct, cod-oil is commended. The signal advantages obtained in the treatment of other neuroses present the strongest arguments for its employment in the one under consideration. Of the strictly medicinal agents, various helpful resources are at command. Strong nerve tonics are demanded. Strychnia, preferably the sulphate subcutaneously, is valuable. Arsenic is a reborant of value. Its power as an efficient nerve-strengthener is indisputable. Ferruginous preparations, especially tincture of the chloride, generously given, are of service. Phosphorus, zinc, quinine, and the minor tonics may be employed as adjuvants. I believe electricity, from its well-known tonic and sedative properties, to be well adapted to the treatment of this disease.

The invigorating effects of cold-water baths, simple or salt, sponge or shower, followed by a liberal amount of friction, are serviceable. The value of alcoholic stimulants is a mooted question, by some condemned as worse than useless, by others esteemed. Regarding this point, individual peculiarities are to be respected. Important auxiliary aid may be secured by a judicious employment of exercise, especially pedestrian.

For the sorely-besetting alvine torpor, atropia is the remedy *par excellence*. Hypodermically administered, $\frac{1}{100}$ to $\frac{1}{60}$ gr. at bedtime, it has, in my experience, always secured relief. It possesses additional value in restraining the excessive cutaneous action resulting from the opium withdrawal, and is, besides, a stimulant of unquestioned power to the sympathetic nervous system, which bears in large measure the brunt of this disease.

Of the suffering ensuing when the tolerant point is

reached, that connected with a want of sleep stands prominent. The insomnia is at times so decided as to defy relief, save by a temporary resort to opium. Of hypnotics, my preference is for chloral, but it sometimes needs dispensing with a lavish hand. I have given thirty, forty, fifty, and sixty grs. consecutively, of a night, before the agrypnia subsided. Bromide of potassium is valuable, but it must be given freely—one to three drachms in the twenty four hours. A point of importance is to administer it during the day, that its effect may be cumulative at bedtime. The other bromides are of service. A combination is sometimes advantageous. Monobromide of camphor commends itself. The lesser soporifics—hashish, henbane, ether, lupulin, and valerian—have a value. The warm bath is sometimes effectual. I have seen sleep secured by the inhalation of a very small quantity of chloroform. When everything else fails, a full dose of the accustomed opiate is advisable.

The intense epigastric distress, the neuralgia-like aches and pains, and the almost insupportable sense of general discomfort, are rendered more endurable by the employment of warm baths, local or general, of simple water, or with vapor or air, as in the Roman or Turkish. They are unquestionably of great restorative value.

The resultant diarrhœa, unless excessive, demands no special attention. When required, warm-water enemas, with mercurials and mild astringents, are indicated. In the attention thus given the body proper, that directed to the mind is of thorough importance. In an affection in which the phenomena of perturbed mental action are so conspicuously prominent, the value of psychical treatment is at once apparent. With its details I need not detain you. Suffice to say they comprise such social surroundings and sustaining sympathy as will tend to reanimate the prostrate spirit, so that, with renewed physical strength and restored will power, life in its pristine integrity may be resumed.

Progress of Medical Science.

Entozoa of the Elephant.—Mr. T. Spencer Cobbold recently examined the viscera of an elephant who had died of an epidemic disease, and found that the entozoa in the stomach and intestines of the animal were a sufficient cause of death. The small intestines contained large quantities of strongyles, considered by Dr. Baird as new to science, and the colon was filled with thousands of amphistomes, or *mauri* as they are called by the natives. The excessive ecchymosis observed throughout the alimentary canal testified to the injurious action of both species of entozoa. Mr. C. says there are now four or five distinct species of entozoa infesting the elephant. The amphistomes under the microscope present a brilliant pink color, with tubercles projecting from the interior of their capacious ventral suckers.—*The Lancet*, Sept. 16, 1876.

Two New Instruments for Treatment of Strictures of the Urethra.—Dr. Giberson, of Brooklyn, calls the attention of the profession to a divulsing urethrotome and a bulbous urethrotome, designed by himself, which he thinks possesses several advantages over All the urethrotomes at present in use. The first is especially designed for the treatment of strictures of large calibre. It consists of a metallic tube nine inches long and eighteen millimetres in circumference, which presents a raised band or shoulder five-eighths of an inch from its extremity. This is split throughout one-third of its length, to permit the halves to be expanded laterally. Within it is a steel tube into which, at one end, an olive-shaped bulb can be screwed, whilst at the opposite end is a screw, turning which retracts the bulb and dilates the instrument. There is a deep slot in the bulb for the blade, the shaft of which passes through the inner tube. The blade can be exposed between the bulb and the shoulder, a distance of five-eighths of an inch. The instrument is supplied with two blades, and three bulbs of different sizes. Each bulb has a flexible copper tip, to enable the instrument to traverse the deep urethra, even to enter the bladder. The aim of the instrument is to avoid deep incisions, but by a process of combined stretching and nicking, to effect divulsion of strictures. In using it the bulb will first discover the stricture, and must be passed through, until the constricting band lies between it and the shoulder; a few turns of the screw will now expand the bars and put this band on the stretch, and the blade, which has hitherto lain concealed in the wedge, must then be retracted so as to traverse the part across which the band lies. Usually this first incision causes a sensible relief of tension, but it rarely severs the stricture completely. A few more turns of the screw will again make this tense, and then the blade must be pushed back to the bulb, again nicking and probably severing the band. If necessary, this procedure may be repeated again and again, until the stricture is completely divided. Several strictures may be divided at the same sitting, if desired. The breadth of the dilating bars renders them less liable to contuse the urethral walls, and the lateral dilatation by stretching the constricting band at right angles to the knife, renders the division easy. On this account it is not necessary to dilate the urethra as excessively as with Dr. Otis' instruments. The dilatation occurs only at the point of constriction. The operation is not very painful, and the hemorrhage is not great. A full-sized sound must be passed for a few days after the operation. One great advantage of this instrument is, that it fixes the stricture at the precise point where the blade projects. Finally it is simply constructed, strong, easily cleansed, and not expensive. Dr. Giberson has employed it with much satisfaction in a large number of cases.

His second instrument consists of a metallic tube, to one end of which is attached one of a series of grooved bulbs of various dimensions. Through the tube passes a steel rod, one end of which is a blade half an inch long, which is concealed until required. The instrument combines the merits of a bulbous bougie and a urethrotome. In using it, the bulb must first be passed through the stricture, and the knife pushed forwards and made to surmount the most prominent part of the bulb. The instrument is then drawn outwards and made to cut its way through the stricture. If a single incision be insufficient, a larger bulb may be substituted and the procedure repeated. If the stricture be very tight, or it be necessary to relieve sudden retention of urine, the bulb is replaced by a flexible, tunnelled tip, which is slipped over a whalebone guide previously introduced. A larger blade is then projected, and the stricture divided. Dr. Giberson believes, however, that stricture below 20 French, are more satisfactorily treated by gradual dilatation, when practicable.

Contraction of the Palmar Fascia.—Dr. O. W. Madelung, of Bonn, has, during the last few years, examined and observed the treatment of a number of cases of this affection in the Surgical Hospital in that

city. In several of the cases he obtained histories of previous injuries or inflammations of the palmar aspect of the hand, and thinks that these were the exciting causes of the subsequent contraction. In other cases, and especially those occurring in advanced age, the disappearance of the fat which fills every interstice in the palmar fascia during early and adult life, seemed to be at least a predisposing cause of the affection. By this disappearance of fat, parts of the tense connective tissue of the palm are left unprotected, and the constant pressure, especially opposite the heads of the metacarpal bones and the flexor tendons, leads to chronic inflammation, to a hyperplasia, and finally shrinking of the normal fibres and consequent permanent flexion of the fingers. The disease claims imperatively the help of the surgeon, both on account of its painfulness and of the inconvenience resulting from the deformity. The standard surgical hand-books mention several operations for its relief, but unfortunately none of them offer any guarantees of success, and they are, moreover, so often followed by obstinate inflammation and ulceration, that they are now generally discarded by surgeons of experience. Prof. Busch, of Bonn, however, has devised an operation that has produced several cures, and has never produced any injurious consequence. It consists in raising a triangular fold of skin, the base of which falls in the furrow separating the bent finger from the palm of the hand, and the apex is at the furthest point in the palm, at which diseased fibres of the connective tissue can be felt, when the finger is extended to the uttermost extent. The flap is dissected up from the apex, as much as possible of the subcutaneous tissue being taken with it, so as to freely expose the palmar fascia. The flexion of the finger will now yield a little, and small nicks must then be made in the fascia, wherever the tension reveals contracted fibres, until the finger can be completely extended. The edges of the wound are then loosely united by sutures and the hand kept in a sling without attempting to preserve the extension. When the wound has granulated entirely, slight extension may be begun by placing wood cylinders of various sizes in the hand, and later on the hand may be stretched on a posterior splint, and active and passive movements may be made while dressing the wound. If several fingers be affected, two fingers may be included in one flap, but it is well not to attempt more in one operation. Advanced age is no counterindication to the operation. It has never been followed by burrowing of pus, or inflammation of the sheaths of the tendons, or by tetanus. On one occasion part of the flap sloughed, probably from too early attempts at stretching. The operation relieves the tension and flexion completely, but does not prevent the occurrence of the malady in another situation. It is important not to begin movements, or to bind the hand on a splint, before the complete formation of granulations in the wound, as this would cause pain and swelling of the hand, and perhaps sloughing of the flap. In 1858, Busch called attention to the great elasticity of granulations, of which he has often taken advantage in the treatment of cicatrices from burns.

Treatment of this contraction by means of manual or mechanical extension without operation, has been tried time and again, but it seems to be utterly useless, and has only resulted in aggravating the pain. Several operations may be necessary to effect a cure. The operation will be greatly facilitated by the use of Esmarch's bloodless method, and the wound be made to heal more rapidly by the use of Lister's antiseptic dressing. When this dressing is used, even if the sheaths of the tendons be injured, which will unavoidably happen in some cases, the tendons may remain perfectly free and unimpeded in their motions.

Mode of Termination of the Tactile Nerves.—Up to the present time, as is known, our information concerning the terminations of the tactile nerves is limited to the knowledge that a portion of these nerves end in terminal corpuscles, particularly the tactile corpuscles of Meissner, and the terminal bulbs or corpuscles of Krause; it is admitted that the remainder terminate either freely or by closed networks.

Dr. Ditlevsen offers to show that the researches of latter years permit of views which are quite distinct and much more satisfactory from an anatomical as well as physiological point of view. With this object, he has reviewed all the researches which demonstrate the termination of the tactile nerves in terminal cells. These researches are the following: 1. The observation of Leydig that the nerves of the tactile hairs terminate by special cells, which are situated in the sheaths of the roots of the hairs, an observation whose truth was confirmed many years later by Sertoli. 2. The observation of Merkel on tactile corpuscles in the tongue and beak of birds. These corpuscles are, in reality, nothing but groups of terminal nervous cells. 3. The discovery by Leydig of similar tactile corpuscles in the skin of reptiles and amphibia 4. The fact that in man the corpuscles of Krause are also groups of terminal nervous cells (Longworth and Waldeyer). 5. The investigation by Longerhaus of amphixus lanceolatus. 6. That of Merkel of the skin of man, mammalia, and birds; and, 7. That of Ditlevsen of the skin of frogs. All these investigations show that the nerves of the skin terminate by special terminal cells. If we add the observations, according to which the tactile corpuscles of man and also the terminal corpuscles of birds, ordinarily called Pacini's corpuscles, are also probably groups of terminal cells, as well as other special observations, mentioned at length by our author, it becomes apparent that the principal characteristics of the mode of termination of the tactile nerves in man and the vertebrates are as follows: 1. The tactile nerves end in cells. 2. They are situated in the skin and the adjacent mucous tissues. 3. They are spread over the entire body; and 4. Are specially numerous in the active organs of touch. 5. The corpuscles of Meissner and Krause are nothing but aggregations of such cells. The result of a critical examination of the investigations thus far made on this subject shows that the reduction of gold chloride is particularly liable to lead to error. Hence the opinions now prevailing are regarded as extremely problematical.

Finally, special attention is paid to certain terminations of nerves, the nature of which as tactile nerves is still undetermined, namely: (1) the corpuscles of Pacini in man and the mammalia, which have been more particularly discussed by Axel Key and Retzius; (2) the organs of the sixth sense of Leydig. These organs are not, according to the author, organs of a special sensation, as Leydig maintains, but are in part terminations of gustatory nerves (the gustatory bulbs of man and the vertebrate animals), in part terminations of tactile nerves, as well as probably the organs discovered in the skin of reptiles by Leydig and Cartier. As to the lateral organs of fishes and tadpoles, it is still doubtful to which of the two abovementioned categories they belong, but it is certain that there is no probable reason for admitting them to be organs of a sixth sense.—*Nordiskt Medicinskt Arkiv*, 8dc. Bd., No. 11.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

THE METRIC SYSTEM IN PRESCRIPTIONS.

THE recent action of the Medical Society of the County of New York, in recommending its members to employ the metric system in writing prescriptions, is likely to attract a good deal of attention, not only in this city, but throughout the country at large. The subject is one which merits the most serious consideration of all who are familiar with its bearings. The proposition to alter a long-established custom is defensible only upon the ground that the substitution is demanded upon the score of necessity, or upon the plea that the merits of the innovation overbalance the demerits, and more than make up for the inconvenience connected with its introduction. Two subsidiary questions likewise demand discussion, namely: Are we ready for the change, and is there a fair prospect of its general adoption? These points appear to us to be the principal ones to which attention should at present be directed, and it is to the consideration of these that we would invite our readers. First, is there any necessity for a change? In other words, is the present system of prescribing in every respect satisfactory, and are our prescriptions dispensed by apothecaries in a proper manner? In ordinary prescribing we employ several different units, to wit, the grain, scruple, drachm, and ounce as measures of weight, and the fluiddrachm fluidounce, and pint as measures of capacity. In England they likewise employ corresponding measures of weight, and also measures of capacity bearing the same names as those in use with us, as the fluiddrachm, fluidounce, pint, etc., but the names do not mean the same. The fluidounce of England is a volume which will be occupied by 437.5 grains of water, twenty of which volumes constitute the pint, while the fluidounce of this country weighs 455.6 grains, and 16 ounces make a pint. This difference is a source of inconvenience to us in two ways: firstly, in reading English books we cannot effect the reduction from their standard to our own (in cases where we wish to be exact), without considerable trouble; while a second and much more serious inconvenience, however, arises from the fact that English made graduates are said to be imported, and employed by pharmacists in this city and elsewhere. In consequence of this the physician who orders a f. ℥i. of any preparation never knows whether the patient will receive the amount that he desires, or whether a less amount will be dispensed to him. This uncertainty, due to the fact that measures of the same name do not possess equal values, is certainly an evil which demands correction in some way. There is, however, still another difficulty in the use of the *ounce*. In the majority of prescriptions calling for fluid preparations the letter *f* is not placed before ℥ symbol. In these cases it is the druggist's duty to supply a Troy ounce, or 480 grains of the preparation demanded. Now what is the custom in this regard? If the prescription goes to an American pharmacy, the probabilities are that the fluidounce (either American or English as may happen) will be employed; on the other hand, if it goes to a German druggist, the probabilities are equally great that the Troy ounce will be used. One prominent pharmacist informed us that it was his custom to use the fluidounce in dispensing prescriptions written by American physicians, and the Troy ounce in dispensing those which came from Germans. We see, then, that when ℥i. of a given solution of morphine is ordered, there is a good deal of uncertainty as to the amount that will actually be dispensed. Another inconvenience connected with the use of graduates is due to the fact that it is extremely difficult to measure with them accurately, even where a reasonable degree of care is exercised; and yet how many of us have watched the nimble fingers of the apothecary pour a tincture into a graduate, and then, after a hasty glance, that would do credit to a pigeon-shooter, pour it into the dispensing bottle, and leave behind a half drachm or so, remaining in the graduate. An experienced apothecary states that "errors of half an ounce or more to the pint are of frequent occurrence," * due to this species of carelessness.

Fully appreciating the errors likely to arise from this cause, the last National Convention for revising the Pharmacopœia directed its Committee of Revision to discard all measures of capacity, and to employ only measures of *weight* in the formulation of officinal preparations. These directions of the Convention, however, were not complied with, and the committee offer as an excuse that compliance therewith would have cost them (the committee) "too much time and trouble." (*Vide* Preface to the Pharmacopœia of the U. S., 1873.)

Thus far we have conceded the accuracy of the graduates themselves. If any one, however, will con-

* We avail ourselves here and later of some of the documents which were presented to the *Comitia Minora* of the County Society.

sider the low price ($3 a dozen), at which ounce graduates can be purchased, he will, we think, come to the conclusion that very little time or trouble has been spent upon their correct adjustment. We once personally had an opportunity of observing the process of graduating and engraving these glasses, and have often wondered whether our own prescriptions were dispensed from them. In many cases, it is true, the inaccuracy of the graduate will be balanced by the inaccuracy of the apothecary, but in other cases this error will be increased.

In our next we will consider the character of the Troy weights in use among us, as bearing upon the general discussion.

ALBANY ETHICS.

Until it is definitely settled that the professors of medical colleges have greater privileges of violating the Code than are accorded to ordinary members of the profession, we shall protest against the shameful system of medical advertising which shields itself behind college announcements in the secular papers. Why any body of men, because they may constitute themselves a faculty of a medical college, have a right to parade their professorships, ostensibly for the good of the institution, but in reality for the good of themselves, we can never quite understand.

As we had a right to expect better things of the Faculty of the Albany Medical College, we are the more surprised to find it stooping to the special method of advertising to which we have referred. We are well aware that any charge of using unfair means to advance the school, and through the school to advance themselves, will be met by the interested parties with innocent astonishment; but this will hardly receive its wished-for interpretation by the profession at large.

There is in reality no middle ground to take in this matter. Either the Code has to be altered to suit the supposed requirements of the college, or the college made to conform with the requirements of the Code. The deliberation which has apparently dictated the policy of the school in the advertising affair, only adds to the gravity of the offence, and the sooner the faculty is subjected to discipline the better. It matters not who the members of the said faculty may be; the higher their position, the more effectual will be the example which may be made of them.

Transactions of the International Medical Congress.—Subscriptions for the forthcoming volume of Transactions of the International Medical Congress are now being received. As but a limited edition will be printed, gentlemen who desire to obtain copies are requested to forward their names, with the amount of subscription ($6 per copy, in advance), to the Treasurer, Dr. Casper Wister, 1303 Arch Street, Philadelphia, before January 15, 1877. The price of the volume will be raised upon the day of publication.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Nov. 8, 1876.

Dr. Charles K. Briddon, President, in the Chair.

BUTTON REMOVED FROM THE NOSE.

Dr. Louis H. Sayre exhibited a button which had been removed from the nose of a child by means of the forceps devised by Mr. Durham, of Guy's Hospital. Several physicians had expressed their opinion that the foreign body had already escaped, but Dr. Sayre introduced the forceps, and felt the blades strike against something which gave a sensation different from the tissues in that locality, gently separated the blades, grasped the body, which proved to be the button, and drew it out. The case illustrated the use of the forceps for removing foreign bodies through small openings without previous dilatation.

Dr. Sell referred to a case in which several unsuccessful attempts had been made to remove a like body from the nose of a small child, and hoped that the instrument exhibited would afford the surgeon a means for obtaining a more uniform success.

Dr. Briddon thought that the blades of the instrument exhibited were too large to admit of easy introduction into the middle meatus, and that the forceps commonly employed for tearing away polypi of the nose would prove more uniformly serviceable. In cases in which no instrument like a pair of forceps could be introduced, the foreign body might be pushed back into the pharynx.

Dr. A. H. Smith referred to a case in which a button had remained in the nose for four or five months. Several unsuccessful attempts had been made to remove it, but Dr. Smith succeeded by introducing a hooked probe, and catching it into the eye of the button.

Dr. Briddon believed that the hooked probe would more frequently succeed than the forceps.

MAMMARY TUMOR.

Dr. Sands presented a mammary tumor removed that day from a mulatto woman at Roosevelt Hospital. The patient was thirty-eight years of age, and had never borne children. Except for the disease of the breast, she was healthy. Three years ago she first perceived simply a hard swelling, as she stated, upon the inner side of the left nipple, but not involving it. This gave her some uneasiness, but it did not commence to grow rapidly until six months ago. Six weeks ago the enlargement became much more rapid, so that at the time she presented herself, a few days before the operation, the swelling was probably five times as large as it was six months previous. The patient was sent for operation by Dr. Rankin, of Newport. The appearance of the swelling of the breast was singular. The organ was considerably enlarged, but unequally so in the vertical and transverse directions. The vertical measurement was a little more than six inches, while the transverse reached nearly twelve inches. The tumor was movable upon the pectoral muscle; was free from heat, pain, or tenderness; was pretty firm upon the external aspect of the breast, but to the inner side of the nipple was a hemispherical protuberance as large as half of a good-sized apple, in which there could be readily detected a distinct sense of fluctuation. The

areolar of the breast seemed healthy; the nipple appeared normal and was not retracted. The general appearance of the breast was something like that presented when chronic abscess is present behind the gland, and at first Dr. Sands was not certain but that it might prove to be such a condition. The history of the case, however, and the duration of the disease, enabled him to exclude such a conjecture. In order to decide as to the presence and the character of the fluid, if present, a hypodermic needle was inserted at the point where the fluctuation was most distinct, and a syringeful of clear, somewhat reddish liquid was drawn out, which upon examination by the heat test was found to contain albumen in large quantity; the specimen becoming nearly solid. The fluid was quite free from viscidity, and upon microscopical examination nothing was detected except blood-globules, and some corpuscles, the nature of which was not determined. Dr. Sands was at a loss with regard to positive diagnosis. Cancer seemed to be fairly excluded. There was neither cachexia nor enlargement of the lymphatic glands. The skin seemed quite healthy, was not changed in appearance, and was not adherent to the tumor.

The diagnosis seemed to be between adenoma, with the occurrence of cyst due to dilatation of one of the ducts of the glands, and a sero-cyst. He was inclined to regard the case as one of the latter. On the day of the operation, to make diagnosis more certain, the tumor was tapped, as a preliminary measure, with a trocar, intending, if it should prove to be a sero-cyst, to withdraw its contents, and inject the cavity with a solution of iodine. After the escape of about four ounces of fluid, serous in appearance, it became evident that the cyst was only incidental, and was not the characteristic part of the disease, for after the removal of the fluid, there still remained a large swelling, almost as large as the original. It was decided to remove the breast by extirpation, and the object was accomplished without difficulty, although he was somewhat surprised to find, upon making the dissection, that the tumor had contracted some adhesion to the skin.

The specimen was presented because it exhibited a somewhat extraordinary appearance. Nearly the entire mass had undergone what appeared to be cheesy degeneration. There was a cyst at the right extremity of the tumor, and it did not seem to have any distinct boundary wall. Its contents seem to have been rather the effusion of bloody serum into the texture of the morbid growth than the product of secretion from a cyst-lining membrane, or a cyst wall. The opposite edge of the tumor displayed a tissue which looked very much like ordinary glandular tissue of the breast somewhat œdematous. Dr. Sands inclined to the opinion that upon microscopic examination the tumor would be found to be an adenoma of the cystic variety which had undergone this remarkable kind of degeneration, yet he was doubtful regarding its precise character. It was a tumor, however, which, prior to the time of possessing any accurate knowledge concerning such growths, would have been called encephaloid. But that term, at the present time, possessed no meaning when applied to such growths without a more minute examination.

The specimen was referred to the Committee on Microscopy.

Dr. Beverley Robinson presented two small portions removed from a growth in the larynx of a man, 31 years of age, who came under his observation three weeks ago at the Manhattan Throat Hospital. At the time the first examination was made with the laryngoscope, the nature of the growth was not decided. The man was also seen by Dr. A. H. Smith, who was also in doubt regarding the nature of the growth. Small portions had been removed, and appeared under the microscope to be of an epitheliomatous character. Since the patient had come under his care there had been considerable advance in the growth, and a certain amount of dysphagia and dyspnœa had been developed.

There were three interesting points in the case:

First. The age of the patient. As far as the doctor was aware, no case of epitheliomatous tumor in the larynx, occurring at the age of 31 years, had been reported.

Second. The question of enlarged lymphatic glands at the base of the jaw and about the neck was not sufficient to determine the nature of growths in the larynx, whatever they may be with regard to tumors in other parts of the body. In other cases enlargement of the lymphatic glands in the neighborhood of the growth had been regarded as characteristic evidence of malignancy.

Third. The appearance the tumor presented under the laryngoscope, and the date of its duration, being of only eighteen months' standing, would seem to indicate its malignant character. At the request of Dr. Robinson, the specimen was referred to the microscopical committee.

Dr. A. H. Smith inquired whether epitheliomatous growths were accompanied by secondary enlargement of the lymphatic glands.

Dr. Satterthwaite replied that such enlargement almost necessarily accompanied such growths in their advanced stages.

Dr. Smith asked if it was not a fact that epitheliomatous growths of the œsophagus were not accompanied by such lymphatic enlargements.

Dr. Satterthwaite was unable to answer with reference to the glands in the immediate region of the growth, but was certain that epitheliomas of the œsophagus were liable to be accompanied by distinctly cancerous growths in other parts of the body.

Dr. Sands recalled a case, reported to the Society some thirteen years ago, in which an undoubted cancerous growth of the epithelial variety was removed from the larynx and returned in the supra-renal capsule, kidney, and ureter on one side, as proved by autopsy made twenty-one months after the operation. There was no enlargement of lymphatic glands in the neighborhood of the larynx.

Dr. Erskine Mason referred to a specimen of cancer of the œsophagus which he had presented to the Society about two years ago, and in that instance the glands were involved, as well as some of the other organs.

Dr. Satterthwaite remarked that at the time the specimen was presented, the observation was made that a small focus might give rise to a very extensive cancerous degeneration of other glands and organs.

Dr. V. P. Gibney presented a specimen, accompanied by a written history.

Aneurism of the Arch of the Aorta with Eroded Portions of Sternum, Clavicle, and First Rib within the Sac—Death by Exhaustion.

Through the kindness of my friend M. T. Scott, a medical student from Lexington, Kentucky, I am enabled to present this comparatively rare specimen. The case occurred in the practice of Dr. Henry T. Skillman, of the same city, and from Mr. Scott, his pupil, I have learned the following history, which he gives me from memory:

A merchant, æt. 33 years, always enjoying good health prior to the summer of 1873, applied to Dr. Skillman for advice in May, 1875. A small tumor was found in the right supraclavicular space, near the middle line, about the size of a common walnut. A distinct pulsation could be perceived, but no marked bruit was appreciable. The patient complained of pain darting down the right arm, and represented this as paroxysmal in character, at times very severe. He was easily excited, and beyond an expression indicative of great anxiety nothing specially attracted attention. The tumor had appeared only a short time before this examination, though the pain in the right arm and a flushed face on the least exertion, had existed for two years.

A positive diagnosis was not made at the time, but the case was observed with much interest by several medical gentlemen. A month or so later a huskiness of voice, with a peculiar cough, served to render clear the diagnosis, the tumor meanwhile continuing in statu quo. No well-marked changes occurred until the last week in August of same year, when Dr. S. was called to see the patient, and found him seated in a large chair suffering from severe dyspnœa, while the tumor seemed the size of a large orange, hanging as it were over the suprasternal notch, and hiding from view the manubrium. Great emaciation, marked huskiness of voice, a cough attended with a difficult expectoration of a glairy mucus, and an alarming dysphagia, were prominent symptoms. The pulsations were visible on entering the room; the skin at one portion was a little discolored, but no other signs of impending rupture were discovered. The dysphagia increased, and finally on the 13th of September death by exhaustion ended his suffering.

Autopsy.—On removing the integument no opening could be found leading into the tumor. On opening the tumor, it was found filled with coagula, and, on inserting the fingers, *roughened pieces of bone* could be distinctly felt. On further investigation the sac was found expanded into two pouches, one springing from the ascending portion of the arch and spreading towards the right, while the other involved the transverse portion, and extended anteriorly and to the left. All of the manubrium—save the upper border, which was jagged—was found within the sac; while the external periosteal layer formed a portion of the lining membrane of the anterior wall. This made, consequently, a consecutive or diffused aneurism. A nearly vertical, irregular fracture of this bone was found. The sternal end of the left clavicle, as far as the junction of the inner with the middle third, with a cup-shaped erosion of the head, the articulation being unaffected, was likewise found within the sac. The inner surface of the sternal end of the first rib of the left side, covered with a thin layer of periosteum, lay within the sac, while the upper border served as a limit for the downward extension of the tumor. No erosion of the trachea was found. Heart and valves thereof found in a nearly normal condition. Lungs found œdematous, though not markedly so; the bronchial tubes containing a considerable quantity of muco-purulent material. No other organs were examined.

In a hasty reference to the literature at my command, I find only two reported cases of aneurism of the aorta where bone was found within the sac, although Dr. Janeway, in a recent conversation on the subject, informed me that one or two such specimens could be seen in the Bellevue Museum. I have not had time to look them up. The reported cases I shall refer to as briefly as possible. Dr. Dickson (Medical Observations and Inquiries, vol. iii., 1769, p. 57) reports a case wherein death occurred from the rupture of the aneurism externally. The first bone of the sternum was almost destroyed, a large portion of the first rib on the right side, the right clavicle was much eroded, while the left was much diseased. *Several small pieces of ragged bone* adhered to the inside of the teguments, and others were mixed among the clotted blood.

Dr. John H. Packard (*American Journal of the Medical Sciences*, July, 1858, p. 48) reports a case wherein the tumor projected through the sternum and opened externally. "Several pieces of roughened bone within its cavity, two of them evidently remnants of the sternum. . . . . bare and eroded." The end of right clavicle and the upper two ribs on same side in a similar condition projected through the walls of the sac. Dr. Packard gives a diagram which represents very clearly his theory of the mode in which the bones found their way into the cavity.

Cases where absorption of the bone takes place from pressure are very common, and many reports of such can be found in the text-books and journals.

PERI-HEPATITIS AND CIRRHOSIS—A QUESTION OF ETIOLOGY.

Dr. A. L. Loomis presented a liver taken from a lady thirty-four years of age, who came under his observation in November, 1874. At his first visit the patient stated that, as far as she knew, there was no hereditary tendency to disease in her case. She had always been healthy until two years before he saw her, when she moved from the western part of the State to West Farms, where she contracted intermittent fever, from which she suffered, having chills and fever every two or three weeks during the entire period which had elapsed up to the time of the Doctor's first visit. During that time she had been treated with quinine and arsenic, but without producing other than temporary relief. In March preceding she suddenly became jaundiced, and so deeply that she said the surface of the body looked like an orange. The jaundiced condition continued about two months, during which time she had distinct chills, fevers, and sweats. About the first of June she noticed that she was losing flesh and strength more rapidly than at any time before, and by the first of August she was unable to get out of bed without assistance. The jaundice had entirely disappeared about the first of June. About that time she also noticed, for the first time, that her abdomen was somewhat swollen. The swelling rapidly increased, and by the middle or last of August she was so large that it was troublesome for her to move about. She was then advised to visit Richfield Springs, and was carried there upon a mattress. Very soon after her arrival she began to improve; regained her appetite and gained in strength, and at the end of four weeks all the swelling of the abdomen had disappeared. It had been supposed that the abdominal cavity contained fluid. Her general health improved so much that she flattered herself that she was nearly well. About that time she took cold, had a coryza and some bronchitis, lost flesh and strength, the paroxysms of intermittent fever returned, the abdomen increased in size quite rapidly; and, having seen a large number of physicians and received their opinions with reference to her case, but obtained no permanent relief, she came to this city for aid, when Dr. Loomis saw her.

Her abdomen was very large, contained fluid, and presented the ordinary appearance of advanced ascites; she vomited almost all the food taken; paroxysms of fever occurred every three or four days distinctly intermittent in character; and it was advised that the fluid be at once removed from the abdominal cavity by tapping. The patient was tapped, and on exami-

nation immediately after the operation, disclosed the fact that the liver was very much diminished in size. The other organs of the body, as far as it was possible to reach them, were found to be in a healthy condition. The urine gave no evidence of renal affection. She was a lady who had never taken stimulants; had never suffered from any form of trouble about the liver, as far as she knew, until the occurrence of the jaundice. After the removal of the fluid she was placed upon tonic treatment, cod-liver oil, iron, etc.; improvement in her condition began; the stomach retained food; she gained in strength and flesh somewhat, but the fluid returned quite rapidly, so that by the middle of December it was thought tapping would again be necessitated. To the surprise of all, however, the abdomen began to diminish in size, and diminished very rapidly, so that by the middle of January the fluid had almost if not entirely disappeared, and the patient was apparently far on towards complete convalescence. Improvement continued so marked that Dr. Loomis discharged her as a regular patient. About the first of March she took cold again; had a coryza and bronchial catarrh; complained of some pain over the region of the liver; fluid again accumulated in the abdominal cavity; she lost flesh and strength, the paroxysms of intermittent fever returned, and about the first of May it became necessary to tap her a second time. The patient did not rally as well as after the first tapping, and by the first of July it became necessary to perform the operation the third time. At each tapping, from 27 to 34 pints of fluid were removed. It was clear each time, contained no floccules of lymph, and, as far as it was possible to determine, had all the characteristics of fluid found in the abdominal cavity in connection with cirrhosis of the liver. After the tapping in July, the patient improved somewhat, but by the middle of November the abdomen was larger than ever, and her general condition was worse, if possible, than it had been at any time during her entire sickness. She was again tapped, and the fluid did not return to much extent, if at all, and by the middle of December her strength and flesh had so increased that she was again discharged as a regular patient. She continued to improve, and the case was regarded as one in which a most remarkable cure had been effected. During all this time the treatment was tonic; at no time resorting to diuretics or hydragogue cathartics, or calomel, or large doses of quinine. About the first of May she was again seen, when she appeared well, and there had been no return of the swelling. About the first of June, Dr. Loomis was called to her on account of an attack of hematemesis. One attack was rapidly followed by others, and at the end of four or five days the patient died of exhaustion.

At autopsy, the liver was found to be much smaller than normal, and the capsule very much thickened. All through the substance were evidences of marked increase of connective tissue—the cut surface presenting the appearance of ordinary cirrhosis with degeneration of liver-tissue. The surface of the organ was smooth rather than lobulated, and apparently the greater change in the connective tissue was upon the surface, the secondary change being in its substance. The stomach, pancreas, and liver were quite firmly bound to each other by old adhesions, but there was no evidence of peritonitis at any other point over the surface of the peritoneum. The only evidence of peritonitis was that indicated by the connective-tissue increase over the liver itself.

If the fluid in the abdominal cavity was the result of peritoneal inflammation, the peritonitis was a localized one. Again, at no time did the fluid withdrawn contain any floccules of lymph or any inflammatory product, indicating that peritonitis was the cause of the appearance.

If the case was one of pure cirrhosis it was regarded as interesting: first, from its origin; and second, from its course; the patient making recoveries to apparent health, which were followed by a return of the dropsical accumulation. The return in each instance was preceded by an attack of coryza and bronchial catarrh, some pain over the liver, and then followed a rapid accumulation of fluid in the abdominal cavity. As the early history of the case was glanced at, it would seem that the first thing that attracted attention to the liver was an acute attack of jaundice, unaccompanied by any symptoms which would lead to the suspicion that it was caused by biliary calculus. It was a jaundice that would lead rather to a catarrh of the gall-ducts as a cause.

Might not the jaundice, then, have been produced by an obstruction in the bile-ducts, in consequence of simple catarrh occurring in a liver already hyperæmic as the result of chronic malaria, and might not an inflammatory process be established in connection with those changes? That being the case, might not the connective-tissue changes have been preceded by thickening and contraction of the covering of the organ, and a gradual extension of that change along the transverse fissure and portal canals until the organ became very thoroughly the seat of connective-tissue degeneration? To Dr. Loomis that seemed to be the only reasonable explanation. The case had been regarded as one of cancer, chronic peritonitis, ovarian tumor, etc., but after the first tapping he was satisfied that it was one of cirrhosis of the liver. When his diagnosis, however, had been made, there remained a doubt with regard to the cause, for the influence of alcohol could be positively excluded.

Dr. Mary Putnam-Jacobi believed that there was no question with regard to the cirrhosis being developed from the peri-hepatitis, for that was a very common cause; but she thought a link had been dropped in arriving at the conclusion that the catarrh of the bile-ducts and jaundice had been caused by the peri-hepatitis. It seemed to her that the catarrh should be explained in some other manner.

Dr. Loomis remarked that he had been misunderstood with reference to the catarrh of the bile-ducts being caused by the peri-hepatitis. Early in the history of the case there was pain over the region of the liver, and at the time of the occurrence of the jaundice the question arose with reference to the probable relation existing between peri-hepatitis, the occurrence of the malarial paroxysms, and the jaundice.

Dr. Loomis further referred to a point of interest in his case. A few years ago Dr. Murchison stated that waxy degeneration of the liver was of quite frequent occurrence in connection with chronic malarial poisoning. At the time the statement was made, Dr. L. had under observation a case of ascites, associated with chronic malarial poisoning, and he made the diagnosis, based upon the statement of Murchison that there was waxy degeneration of the liver with ascites as the result. The patient died, and at the autopsy no waxy degeneration whatever was found, but there was present just such a cirrhotic condition of the liver as seen in the specimen presented, but without any history of jaundice.

With regard to the jaundice in his present case, it had no necessary connection with the peri-hepatitis; but, occurring at the time of the first pain over the liver, and the pain over the liver occurring in con-

nection with paroxysms of intermittent fever, it would seem that there was a connection between the two causes which might in part explain the development of an inflammatory process throughout the substance of the organ.

Dr. A. H. Smith inquired whether the paroxysms of intermittent were controlled by quinine.

Dr. Loomis replied that they were not entirely controlled.

Dr. Beverley Robinson asked whether there was not ancient pleuritis in Dr. Loomis' case.

He had seen cases in which there had been present pleuritic trouble, a thickened condition of covering of the liver, accompanied with intermittent paroxysms of pain and fever. They had evidently been cases in which the pleurisy was the original disease, and peri-hepatitis had been developed secondarily. He regarded it as impossible to differentiate between peri-hepatitis and pleurisy upon the right side without resorting to puncture of the chest.

Dr. Loomis replied that there were no evidences of pleurisy in his case, and furthermore, that he regarded it as an easy matter to make a differential diagnosis between peri-hepatitis and pleurisy—and without puncture.

Dr. Putnam-Jacobi directed Dr. Loomis' attention to the fact that a calculus was present in the gall-bladder.

Dr. Loomis recognized its presence, and remarked that whether it had anything to do with the production of the jaundice was a question.

NEW YORK COUNTY MEDICAL SOCIETY.

Annual and Stated Meeting, November 27, 1876.

Annual Meeting.

Dr. H. B. Sands, President, in the Chair.

THE METRIC SYSTEM.

After the reading of resolutions upon the death of Dr. Thebaud and Dr. Hunt, the following resolution was reported from the Comitia Minora, and adopted by the Society:

Resolved, That the Medical Society of the County of New York recommends to its members the use of the Metric System in their prescriptions.

Dr. Sands, the retiring President, in accordance with custom and courtesy, addressed the Society over which he had had the honor to preside during the past two years, and referred especially to an important event which had occurred within that period of time. The event to which reference was made was the legislative enactment regarding the suppression of quackery. The Censors of the Society had taken action in the matter, and the result of their labors had been quite gratifying. It was not probable that quackery could be entirely abolished by any law. The true remedy was within and not outside of the profession. The significance of a medical diploma should be increased; a higher standard of excellence should be aimed at among ourselves, so that no doubt could be left in the public mind with regard to the superiority and skill of the regular practitioner. Medical men should heartily unite in perfecting themselves in their art, and in proportion as they carried out such resolutions, and approached the highest standard of excellence, would empiricism be expelled by the pure light of scientific truth.

The minutes were then read and approved, and the Society adjourned.

Stated Meeting.

Dr. John C. Peters, President, in the Chair.

Dr. Peters, in his inaugural remarks, recommended that steps be immediately taken with reference to the publication of the Transactions of the Society. The Society had been in existence seventy years, and during all that time the minutes had been kept correctly, and contained a large amount of material which was exceedingly interesting, and he hoped, in view of the fact that the Society now held more money than they were entitled to by law, the Transactions would be published within the year.

It was recommended by the Comitia Minora that certificates of membership be granted to the following gentlemen: Drs. J. L. Wilson, W. B. Hubbard, Gustav B. Sussdorf, J. C. Kendall, David Brekes, and S. S. Bogart.

Dr. Erskine Mason then reported

TWO CASES OF SUCCESSFUL AMPUTATION AT THE HIP-JOINT.

He gave a complete history of each case, and drew largely upon the writings of Dr. George A. Otis, of the U. S. Army, for the statistics and the literature of the subject. The following were some of the more important conclusions to which Dr. M. arrived. It was not the greater dexterity in the performance of this operation that had given the greater success in later years, but it was the more careful selection of cases, and a more careful use of all the appliances which surgeons now have placed at their command. Thoroughly skilled assistants were regarded essential to the best success.

It was desirable that as little blood as possible should be lost. In his cases an abdominal tourniquet was used, and Esmarch's bandage also, so that no more blood was shed than in some comparatively trivial operations. If called upon again to perform the operation he would use Lister's abdominal compressor. The compression of the abdominal aorta should not be prolonged beyond the time necessary to secure the anterior vessels. The posterior vessels could be controlled with sponges until secured with the ligature.

It was believed that rapidity in the performance of the operation did not lessen the shock. Subcutaneous injection of a drachm or a drachm and a half of brandy immediately after severance of the limb was recommended as a measure for modifying the shock and assisting the patient in rallying. The doctor was strongly inclined to the opinion that loss of blood was the leading element in the production of shock; hence should be most carefully guarded against.

The complete removal of the capsular ligament was recommended, for it was believed that, by so doing, the healing of the wound would be expedited, and the formation of sinuses more certainly prevented. The circular operation, or Alanson's, was performed, and Dr. Mason was quite strongly in its favor, because the stump could be more easily dressed than after the flap operation; it probably gave rise to a smaller suppurating surface; it gave the opportunity for modification by separating the bone just below the trochanters in cases in which it might be deemed necessary after the bone had been reached, and the vessels not being cut so obliquely across could be more easily secured. There were cases, probably, in which the flap operation would be better than the circular, and the surgeon should not be wedded to either. It was a curious fact, and one which had been placed upon record, that in successful cases of amputation at the hip-joint, there had followed a marked increase in th

weight of the patient. The second of Dr. Mason's patients had gained twenty-five pounds in weight since the operation, and the first had gained considerably. The general conclusion to which Dr. Mason arrived was, that the former mortality attending this operation could be diminished by employing all the resources which an enlightened science had placed at our command, and the prediction was made that it might not be far distant when the results of the operation would be as favorable as those of amputation at the upper portion of the thigh. The patients, a lady and a gentleman, were then presented, the lady having lost her left, and the gentleman his right lower extremity.

After the conclusion of Dr. Mason's paper,

Dr. A. B. Crosby read a memorial upon the lives and services of

FIVE MEDICAL MEN WHO PRACTISED THEIR PROFESSION ONE HUNDRED YEARS AGO.

Two were signers of the Declaration of Independence, namely—Josiah Bartlett and Matthew Thornton. Their field of labor, professionally, was chiefly in the State of New Hampshire.

It was noted that, as early as 1754, Dr. Bartlett treated what is known as diphtheria with great success by the use of antiseptics and free doses of Peruvian bark. The same disease prevailed in the same locality several years previous to the above date, was treated antiphlogistically in a heroic manner, and the mortality was exceedingly great. Dr. Bartlett died at the age of sixty-five, and Dr. Thornton reached the age of eighty-nine.

Joshua Brackett was born in 1733, and died in 1802. He turned his attention particularly to the practice of obstetrics.

Lyman Spaulding was born in 1775, and died in 1821. To Dr. Spaulding was due the credit of originating the plan for bringing into existence the American Pharmacopœia, and throughout its formation his name could everywhere be traced, for he was, *de facto*, its founder.

Nathan Smith was born in 1762, and died in 1829. He was the founder of the Medical Department of Dartmouth College; and, with great acceptance to the students, delivered all the lectures. In 1798 he burst forth from the prejudices so strongly held by the profession and the people, and used cold affusion in the treatment of typhus fever; gave his patients cold water to drink, plenty of fresh air, insisted upon perfect cleanliness, and granted a nourishing and moderately generous diet. He was among the very first to perform the operation of ovariotomy in this country, and performed it independent of any knowledge of McDowell, of Ky. He used leather ligatures, cutting the stump square across, secured the vessels as after any other amputation, and returned the whole to the abdominal cavity. His patient made a good recovery, although there were some omental adhesions which necessitated the use of additional ligatures, and there were also some adhesions to the abdominal walls. Manipulation for the reduction of dislocation at the hip-joint was also among his accomplishments.

Dr. Crosby closed with a glowing tribute to the memory of these five heroes in the medical profession.

Dr. O'Sullivan introduced a resolution relating to the publication of the Transactions of the Society, which was referred to the Comitia Minora.

On motion, the By-laws were suspended, and the second Monday evening in December designated as the time for holding the next Stated Meeting.

The Society then adjourned.

New Instruments.

STOMACH PUMP, ASPIRATOR, AND SYRINGE.

By B. A. WATSON, M.D.,

SURGEON TO JERSEY CITY CHARITY AND ST. FRANCIS HOSPITALS, JERSEY CITY, N. J.

Having recently, in my hospital practice, a patient requiring the daily use of the stomach-pump, I began the treatment with an instrument somewhat less complicated than a steam-engine. To use this pump successfully, it is necessary for the physician to spend considerable time in the study of its mechanism, and, finally, to demonstrate its action by the passage of fluids through it in either direction prior to introducing the tube into the stomach. These preliminaries having been properly attended to, the tube may be passed, and the physician, with the aid of an assistant, will probably succeed in introducing food into the stomach or removing its fluid contents when desirable.

These complications and high price of the instrument are probably the real reasons why so many physi-

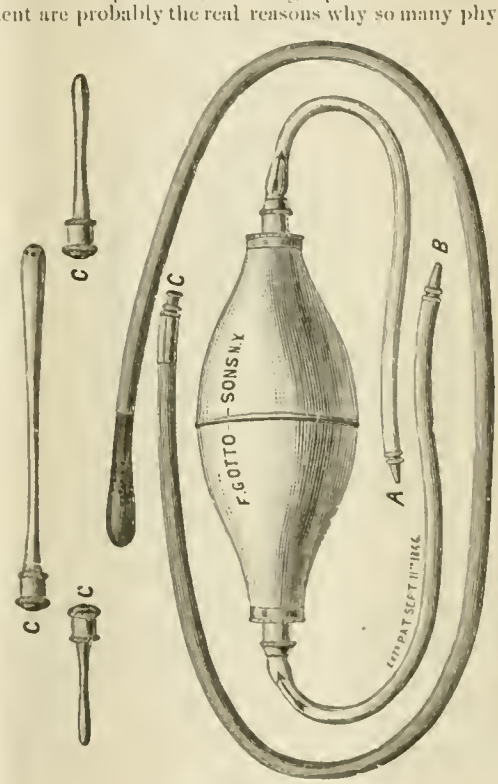

Fig. 1.

A, Cone; B, Cone; C, Sockets.

cians are found to depend upon the uncertain action of emetics whenever they wish to empty the stomach in case of poisoning. For the purpose of removing these objections so far as possible, I now offer an instrument which I have used with satisfaction, after an experience confirmatory of the views already expressed, and which I think may be acceptable to the profession.

The central part of this figure will be recognized immediately as the pump—modelled after Davidson's syringe—increased in size and power, and supplied

with hollow cones for the purpose of facilitating the making the connection. The direction of the current through the instrument is shown by printed arrows on the tubes, which are connected with the bulb of the pump. Surrounding the pump may be seen in this figure the English elastic stomach-tube provided with a metallic socket C, and the other end supplied with a piece of hard rubber, which is filled with fine perforations for the purpose of protecting the valves of the instrument. For the purpose of introducing fluids into the stomach, the cone A is introduced into the socket C, and the instrument worked in the usual way; and if it now be desired to reverse the current, it is only necessary for the physician using the instrument, while he holds the bulb in the left hand, to seize the cone B with the right hand, carry it to the socket, detach cone A, and insert the cone B. Thus the action may be rapidly reversed, and that too while it is filled with fluid, without even the loss of a single drop. The use of this pump as an ordinary syringe requires no explanation.

The following woodcut represents the Aspirator.

Fig. 2.
D, Cone; C, Sockets.

This is prepared for use by closing the tube with stop-cock, attaching the needle to cone D, connecting the cone B of the pump with the socket C of the Aspirator, and then exhausting the air in the bottle, after which the needle may be introduced, the stop-cock opened, and the working of the pump resumed for the purpose of continuing the vacuum.

These instruments are manufactured by Messrs. F. G. Otto & Sons, of New York.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Nov. 25th to Dec. 2d, 1876.

McElderry, H., Asst. Surgeon. Relieved from duty at Fort Monroe, Va., and assigned to temporary duty with the troops at Washington Arsenal, D. C. S. O. 242, A. G. O., Nov. 24, 1876.

Lamb, C. A., Lieut.-Col. and Asst. Medical Purveyor. Died at the Soldiers' Home, near Washington, D. C., Dec. 2, 1876.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending December 2, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

Dr. W. H. Geddings, of Aiken, S. C.—We learn with pleasure that Dr. W. H. Geddings, of Aiken, S. C., has entirely recovered from his recent severe illness, and has resumed the practice of his profession.

Scarlet Fever in a malignant form is very prevalent throughout the West.

Yellow Fever in Savannah.—The *Savannah News* publishes the following table showing the progress of yellow fever, and the mortality from August to November 26th:

	Total Deaths.	Yellow Fever.	Other Dis.	Whites.	Blacks.
August.....	172	33	139	91	81
September.....	783	556	227	575	208
October.....	474	287	187	301	173
November.....	145	64	81	91	54
Grand total.....	1,574	940	634	1,058	516

The N. Y. Medical Library and Journal Association has concluded to hold but two meetings in the month, instead of weekly ones as before. The times fixed are the first and third Friday evenings of each month, at 8.30 P.M.

Harvey Demonstrating the Circulation of the Blood.—The great scarcity of the original engraving of Harvey demonstrating the circulation of the blood to Charles the First of England, and published in 1851, by Lloyd Brothers, of London, has induced Mr. H. Wood, jr., of 826 Broadway, to issue a photograph of the same. The size of the latter is 7x9 inches, and is exceedingly well executed. By comparing it with an original engraving in our possession, we are satisfied that its sharpness of detail is everything which could be expected or desired under the circumstances. As the London engraving is now entirely out of print and not obtainable "for love or money," the photographic copy is likely to become a popular office picture.

Newspapers.—Correspondents sending us newspapers from different portions of the country will please mark the articles, or paragraphs, to which they wish to draw our attention.

Salicylic Acid.—Dr. Martineau reported at a recent meeting of the Société Thérapeutique, that neither in typhoid fever, nor in articular rheumatism, had he obtained any influences either by the temperature or the pulse, by the use of salicylic acid.

The Medical Classes at Philadelphia are said to be larger than those of last year.

Original Lectures.

LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

LECTURE VI.

TYPHOID FEVER (CONTINUED).—TREATMENT.

GENTLEMEN:—Before speaking in detail of the treatment of typhoid fever, I will say a few words concerning its prevention.

If the modern theory (which I have already given you) of its etiology be accepted, the question naturally arises, cannot the typhoid poison be prevented from entering our dwellings, or polluting our drinking-water?

Facts prove almost conclusively that typhoid fever is never of spontaneous origin. Should it occur in the locality where you may reside, if possible find out its origin. If no case has ever before occurred in the locality, endeavor to ascertain the manner in which the typhoid poison has been introduced. If it is already endemic, limit the disease to the first few cases by a most thorough disinfection, and remove all those surroundings which favor the reproduction of the typhoid poison.

If the theory is correct, that typhoid fever is dependent upon a poison contained in the excrements of a typhoid patient, then the poison should be destroyed as soon as it is discharged from the body. For this purpose, the intestinal discharges should be received into a porcelain bed-pan (not a tin one), the bottom of which should be covered with a thin layer of powdered sulphate of iron; immediately after the discharge, crude muriatic acid, equal in quantity to one-third of the fæcal mass, should be poured over it. Never empty the discharges from a typhoid patient (no matter how thoroughly they may have been disinfected) into the privy or water-closet used by the family. Trenches should be dug for their reception, and new trenches should be opened every few days; the greatest care should be taken that these trenches are not so situated that drainage from them can contaminate wells or springs which furnish drinking-water. All under-clothing or bed-clothing that may have become soiled by the discharges from the bowels, should be immediately immersed in chlorine water, and thoroughly boiled within twenty-four hours. This procedure will certainly destroy the infective power of the typhoid poison contained in the intestinal discharges, and in the majority of instances you will prevent the spread of the fever.

Repeated observation shows that when one member of a family has typhoid fever, not unfrequently it is developed in every other member. This spread of the disease can be prevented, unless there is some local cause for its development which cannot be reached.

When its origin is not apparent, the wells, springs, and all the sources from whence water is derived for drinking and cooking purposes should be carefully and thoroughly inspected. Care must be taken that the waste-pipes from wells and springs do not pass directly into cesspools or sewers, and thus become a means for the conveyance of impure gases into the springs and wells.

The greatest care must also be exercised in regard to home drains and sewer-pipes, that they shall be free from leakage and obstruction, and that all water-closets, sinks, and other openings into them be provided with suitable traps.

When unpleasant odors are constantly present in dwellings, especially in sleeping apartments, disinfectants should be thoroughly employed, and the house be kept thoroughly ventilated.

When it may be necessary to open drains and cesspools in a dwelling for purposes of repair or cleansing, the same precautions should be exercised; these are especially of importance during the summer and autumn.

In conclusion, let me impress upon you this fact, that when typhoid fever is carried from the sick to the healthy, the evacuations are the chief, if not the only means of contamination; consequently, the importance of thoroughly disinfecting the excrements of typhoid patients should always be borne in mind.

In this connection the question naturally arises, can we not counteract or neutralize the effects of the fever poison after it has gained admission into the system, and thus prevent the development of typhoid fever? To accomplish this, at one time blood-letting was resorted to; but at the present day few practitioners would venture to suggest such a plan of treatment, and few patients could be found willing to submit to it. Emetics were given on the supposition that the fever poison acted primarily upon the mucous membrane of the stomach, and that the offending agent might be removed by their early administration, and thus its absorption into the system prevented. As it has been proved that the typhoid poison can be introduced into the system through other channels than the stomach, and as experience has shown that emetics have not the power to prevent the development of typhoid fever, their use has been abandoned. Diaphoretics have also been employed; but there is not the slightest proof that typhoid or any fever poison was ever removed from the system by sweating. A patient with some of the premonitory symptoms of fever may sweat, be relieved, and at once recover, but such a patient has not received the typhoid poison into his system, and was not, as is sometimes said, "threatened with typhoid fever."

Notwithstanding the bold affirmation of the author of the cold affusion plan of treatment, that if it were resorted to before the third day of the disease, it would invariably arrest its development, it has failed to stand the test of practical experience.

More recently, sulphate of quinine, administered in large doses, has been thought to have the power of arresting the development of typhoid fever in the same way that it arrests malarial fever, by its anti-periodic power; but there is no evidence that it has any such power, and as a prophylactic remedy it has been abandoned.

I might go on almost indefinitely enumerating measures which have been resorted to for preventing the development of this fever; but after the poison has once gained entrance into the system, no means have as yet been discovered by which it can be counteracted or neutralized so as to prevent the development of this disease. The duty of the physician, so far as he may be able, is to guide the disease to a favorable issue, and prevent injury to organs essential to life, keeping in mind that a certain definite period must elapse before this result can be accomplished.

Before entering into a detailed account of the treatment to be pursued in the management of a case of typhoid fever, I will say a few words in reference to the arrangement of the sick-room of fever patients.

Though often overlooked, this is a matter of no inconsiderable importance, not only as regards the comfort of the patient, but it has much to do with the successful issue of the case.

It is of the greatest importance that a properly qualified nurse be selected; one who has had experience in the care of fever patients is to be preferred. In the next place, the patient should be placed in a large and well-ventilated apartment. All furniture should be removed from the sick-room, except those articles which are necessary for the comfort of the patient and the convenience of the attendants. Remove the carpets from the floor, place your patient in a bed of moderate size in the centre of the room, and let there be free ventilation during both day and night.

The temperature of the apartment (if possible) should be kept below 60° F.

The bed and body linen of the patient should be changed daily, and at once be removed from the sick-room and placed in a weak solution of chloride of sodium; especially is this important if the patient is having frequent discharges from the bowels. The apartment should be kept perfectly quiet, the light subdued, and only the attendants should be allowed in the room.

These preliminary arrangements having been made, we will suppose we have in charge a patient with a mild type of typhoid fever. All medicinal interference in such a case is unnecessary. The treatment resolves itself into the arrangement of the sick-room and proper diet; milk is preferable, fruits are not to be allowed in any case. In the mildest case the care in diet is important, and the patient should be kept in bed until convalescence is fully established. This should be insisted upon, even in the mildest cases.

As I have already stated, the temperature in a mild type of this fever rarely rises above 103° F.; therefore there is no necessity for resorting to antipyretic measures; frequent sponging of the surface with cold or tepid water, as is most agreeable to the patient, will be found of service.

By far the larger number of cases of this fever are of a more severe type, and though in your treatment you must be guided by the circumstances of each individual case, usually you will be obliged to resort to more decided measures.

Remember that there are no specifics for this disease; all of those which have been proposed and employed have either fallen into disuse, or are resorted to only as aids in general treatment.

Typhoid fever is a disease that has certain stages to pass through, limited only by days and weeks. There is great doubt whether the physician can shorten its duration by a single day, but experience warrants the belief that many lives may be saved by remedial measures used at the proper time, and combined with judicious hygienic management.

There are critical periods in this disease; be prepared by knowledge and judgment to carry (if possible) your patient safely through them. Unquestionably one of the most important things to be accomplished is the reduction of temperature, or rather the keeping of the temperature below a certain standard. Blood-letting, emetics, diaphoretics, cathartics, chlorine water, and mineral acids have all been resorted to in order to reduce temperature. The last two agents were supposed to reduce temperature by neutralizing the typhoid poison. At the present day I think there is no intelligent physician who imagines he can neutralize the typhoid poison, and thus reduce temperature, while only a few years ago these agents were supposed to possess such power, and were very extensively employed for such a purpose by some very intelligent physicians.

The agents which more recently have been employed for this purpose, namely, sulphate of quinine and cold applications, are powerful agents in reducing the temperature and lessening the severity of the disease; but they can never shorten its duration, and if you employ them, expecting this result, you will be greatly disappointed. It is claimed by many very distinguished observers of the present day that the parenchymatous degenerations of the different organs and tissues of the body, which are found in those who die of typhoid fever, are due to the prolonged high temperature which is present during the course of this disease; but as yet there are no facts to prove this assertion, for the same parenchymatous changes are found in the bodies of those who have died of diseases, the course of which was not marked by high temperature, and did not extend over a period of more than forty-eight hours. So far as we are able by analogy to determine upon what these parenchymatous changes depend, we are led to believe that the specific poison of the disease has more to do with their development than the high rate of temperature. One thing must be apparent to every clinical observer: that the injurious effects of a prolonged high temperature are early and most markedly shown by disturbances of the cerebro-spinal system. It is still an unsettled question whether these disturbances are due to the primary changes in the constituents of the blood, which always accompany a high range of temperature, or to the direct effects of the high temperature on the nerve centres.

Whichever view we accept or adopt, the employment of those means which have the power of safely reducing temperature is indicated, and when judiciously used they have much to do with the safety of the patient.

All those means which have been employed for the reduction of temperature are included under the general term of *antipyretics*, and the treatment of disease by the use of these agents has received the name of *antipyretic treatment*.

Unquestionably the most efficient and reliable of the antipyretic agents are the external application of cold by means of baths, packs, and effusions, and the internal administration of the sulphate of quinine. The quinine is not administered to produce any specific action upon the typhoid fever poison, but is employed for its antipyretic power. There are other antipyretic agents besides these two, but they are of so little importance that it is necessary to give them only a passing notice after we shall have considered these two important ones.

At the present time, to a great extent, the opinion prevails that the application of cold to the surface is the great antipyretic in the treatment of fever. This is no new teaching. Long ago Dr. Currie recommended the application of cold to the surface of the body for the purpose of rapidly reducing temperature, and proved that it had such an effect; yet it was never very generally practised, and soon fell into disuse, as there was nothing reliable to guide one in its application. As we now have the thermometer to guide us in its application, more recently it has been resorted to with considerable success.

I will give you some general rules, which may be of service to you in the use of this antipyretic in the treatment of typhoid fever.

As soon as the axillary temperature in the evening rises above 103° F., place the patient in a water

bath having a temperature of 70° F. or 80° F., and gradually lower that temperature by the addition of cold water or ice, until the temperature of the patient begins to fall. You may be compelled to lower the temperature of the bath to 60° F. before the temperature of the patient is affected; but the lowering of the body temperature must be accomplished by the lowering of the temperature of the bath, taking care that the latter does not fall below 60° F. When the temperature begins to fall, renew your thermometrical observations every two or three minutes. If it falls rapidly—that is, two or three degrees in five or six minutes—as soon as the fall has reached 103° F., remove your patient from the bath; if it falls slowly, as soon as it reaches 101° F. he should be removed and immediately placed in bed. Never keep the patient in the bath until the temperature shall have reached the normal standard; should you do so, he may pass from a condition of fever into a state of collapse, as the temperature continues to fall for some time after his removal from the bath. While in the bath, cold should be applied to the head by means of a sponge wet in cold water or by an ice bag.

The cold pack is much less effective than the bath; but if the patient is too feeble to be moved, it may be employed with benefit. You should wrap the patient in a sheet wrung out of tepid water, and over this sheet apply one wrung out of cold water. The latter may be removed as often as it becomes warmed; its application and removal may be continued until the desired fall in temperature shall be obtained.

In severe cases, during the first and second weeks, you will find that after the temperature has been reduced by the application of cold to the surface, it will begin slowly to rise until it reaches its former height. Usually one to three hours will elapse before it begins to rise, and from two to six before it reaches its former height. You will then be obliged to repeat the baths or packs, and to continue their use, both day and night, from three to six times during the twenty-four hours, if you expect to keep the temperature below 103° F. and accomplish anything by this plan of treatment. My experience in the use of cold applications leads me to believe that unless you are able to maintain a low range of temperature after four or five baths, you gain very little by their continuance. In other words, if, after using the baths for twenty-four hours, the temperature of your patient rapidly rises to the same or a higher degree than it was before their use was commenced, you will obtain little or no benefit from their continuance unless you can introduce some other agent which shall maintain the low temperature reached by the bath. I am also convinced that after the second week of typhoid fever, cold baths should not be employed to reduce temperature, for by their continuous use after that period they may do great harm. The condition of a typhoid patient during the first and second week of the fever is very different from that during the third and fourth week. During this latter period there is great danger of collapse after a cold bath, and in several instances I am confident that pulmonary complications have been the result. In a few instances the temperature can be very rapidly lowered by the application of ice-bags to the abdomen. The rapidity with which the temperature can be reduced usually depends upon the severity of the fever. In some cases, when the patient is placed in the cold bath, the temperature will immediately begin to fall; in other cases there will be a gradual reduction of temperature as the water is made cooler. In certain severe cases, you may keep a patient in a bath of the temperature of 60° F. for the space of half an hour, without the temperature falling a degree. These cases are exceedingly grave in character, and you should use the bath with great care.

Finally, let me impress upon you that in typhoid fever, in order to reduce the temperature, you must not indiscriminately apply cold to the surface of the body. Perhaps there is no remedial agent which requires greater care in its use; yet doubtless, when judiciously employed, the lives of many typhoid patients may be saved, and it is equally certain that when injudiciously employed, many lives may be destroyed. If you use the cold baths in conjunction with other means for reducing temperature (concerning which I will speak at my next lecture), I am confident you will accomplish much; but if you rely only upon the baths, in the majority of instances you will be disappointed in the result. At the present time it seems to me, that by some, the benefit and power of cold baths in the treatment of typhoid fever have been overrated.

The general condition of your patient, and the stage of the fever must be considered; also the effects of the first few baths must be carefully noted.

Should a patient's temperature range at 104° F. or 105° F., there is no positive evidence that you must resort to a cold bath, or that a cold bath is the best agent to be employed for its reduction. Again, if the patient after the second or third bath is more quiet, has less delirium (if delirium previously existed), if his breathing becomes easy and natural, if the heart's action is more regular and forcible, and he falls asleep and perspires, there can be no question in regard to the beneficial effects of the bath. If, on the other hand, the bath is followed by feebler heart's action, by dusky cheeks, by rapid respiration, and by coldness of the extremities, from which condition the patient rallies slowly and imperfectly, you may be certain that, however high the temperature may range, you will do harm by continuing the baths. When the extremities are cold, or there is profuse hemorrhage from the bowels, or when, from any cause, there is great feebleness of the heart's action, and especially in the case of aged persons, cold baths are contraindicated.

Original Communications.

A CASE OF EXTENSIVE COMPOUND FRACTURE OF SKULL AND LOSS OF BRAIN-SUBSTANCE, WITH OTHER SEVERE INJURIES—RECOVERY.

By CHAS. E. SLOCUM, M.D.,

DEFIANCE, OHIO.

SEPTEMBER 22, 1875. I was sent for in great haste to visit a farm-house, four miles from Defiance, which had just been the scene of a terrific steam boiler explosion. On arriving at the place designated, I found three men dead, killed by the explosion, two with crushed heads, and the other with epigastrium and left side wholly torn open. Several were injured more or less severely. The steam-boiler, engine and appurtenances (being connected so as to be readily portable), weighing 4,500 lbs., were thrown by the explosion a distance of 130 feet, passing through a barn in their course.

The subject of this article, Orville Cassill, aged 15 years, while working in the barn, was struck by the flying boiler and carried with it a distance of 40 feet, where he was found on a pile of straw with the cu-

gine partly resting on him. He was with difficulty removed from under the great weight, and was found insensible and suffering extremely from the shock. His skull had suffered an extensive compound comminuted fracture, and considerable broken-down brain substance was oozing from the wound with very free hemorrhage, which was found to proceed from the lacerated middle meningeal artery. He was removed to the house covered with blankets, warm bricks placed to his feet and cold applications to his head. The shock continued so extreme that scarcely a hope was entertained of his rallying from it.

The heart's action and respiration were scarcely perceptible. There followed, however, a very slow improvement in his condition, and after a lapse of fifteen hours he swallowed some warm fluid placed in his mouth.

On the following morning, twenty-two hours after the accident, many of the symptoms of concussion and compression coexisted to a marked degree. The power of speech was abolished, special sensation destroyed. Respiration still feeble, imperfect and noiseless. Pulse weak, quickened, tremulous, and irregular. He had vomited slightly. There had been involuntary evacuations of fæces and urine. He would swallow small quantities of fluid if placed well back in his mouth. Voluntary muscles much weakened, but able to contract. Pupils widely dilated, nearly uniform, and sensitive to light. Eyelids firmly closed and immovable. Mind abolished.

With the assistance of Dr. L. G. Thacker, who administered chloroform, I proceeded to operate on his head. The fracture involved the right parietal bone in its posterior inferior edge and angle, and extended into the occipital bone. The edges of some of the fractured pieces (two of the largest measuring two and five-eighths inches in length, one, and one and a half inch wide respectively; smaller pieces were numerous) were turned inwards as on a hinge, and had destroyed the meninges to the extent of the fracture and pulpefied the brain substance to a depth equal to their width.

The broken brain flowed away freely before, during, and after the operation of enlarging the scalp wound, removing the pieces of loosened and depressed skull, and trimming the ragged edges. The hemorrhage was still considerable from the meningeal arteries. The chloroform was well borne, the pulse increasing somewhat in volume during its administration, and a quiet sleep followed its discontinuance. The scalp wound was approximated by numerous sutures of silver wire, the head shaved, and long strips of adhesive plaster applied and covered by bandages stitched to their place, leaving several apertures for the exit of broken-down brain-substance remaining and the pus that might form.

Pressure of the brain outward (hernia cerebri) was great and troublesome during the first and second weeks.

The frequent tearing out of the sutures with the very free suppuration, made frequent dressings necessary. The silver wire was repeatedly and freely employed until union took place.

The accident occurred Wednesday morning; Saturday night following he uttered the first sound as he was being moved. Sunday a muttering delirium commenced in which a word could occasionally be distinguished. This delirium increased during the week. After ten days a simple question would occasionally be answered intelligibly in monosyllable. During the third week the hemisphere gradually settled back to its normal position, followed by the scalp and a depression. His mind improved rapidly and his delirium ceased with the ending of the third week.

For over two weeks there was incontinence of urine and fæces, and for the same length of time his nurses thought him blind. His pupils were constantly widely dilated and nearly uniform. Their contraction to a natural size occupied a period of several months, and his improvement in sight—particularly his estimate of distance—was equally slow.

During his delirium, powders containing sulphate of morphia one-tenth grain, and bromide of potassium fifteen grains, were given whenever required. Usually one or two in twenty-four hours sufficed to keep him moderately quiet, and four was the highest number taken. A simple refrigerant drink, with an occasional small dose of sulphate of magnesia, constitute the list of medicines used until tonics were indicated.

Constant watching and frequent restraint were necessary to prevent violence to his head and other injuries.

In November necrosed bone was removed from the anterior part of the wound, and in December a small piece from the occipital bone, the former being a piece found depressed at the first operation and elevated into position, thinking to preserve it.

In December the last flow of brain-substance was noticed at the inferior part of the wound, it following the removal of a small fungous excrescence. The lowest point over the occipital bone was the last to close, frequently exuding a small quantity of pus until April, 1876, when it soundly healed.

This case I think may fairly be classed as one quite fully illustrative of the great amount of injury and consequent dangers that the human system is at times capable of withstanding.

This boy was severely bruised in the left leg and thigh, in the sacral and gluteal regions, in the left scapula, and in the whole extent of his left forearm. Two abscesses formed in his shoulder, and the continued injury given his forearm during his restless delirium produced suppuration and a complete fracture of what was at first an incomplete one of both bones. Necrosis and removal of bone followed. By persevering treatment he recovered with a straight, serviceable arm, with good motions.

During the summer just passed he has been assisting his father in errands and light work.

His mental faculties are a little slow in their action, and somewhat impaired. His parents state that he is much more petulant than he was before the injury. There is no complaint of pain.

The depression through the opening in the skull varies considerably in depth, at times measuring one inch, notwithstanding the increased thickness of the scalp. He cannot remain in a stooping posture. He is in good flesh and strong, but still moves a little sidewise and has not recovered his former steadiness of walk.

This case is also good evidence in favor of an opening through the scalp and skull sufficient in size to allow the full escape of broken brain, blood and pus in all perforating and contusing injuries of the cerebral mass.

The history of the case of Carruth, of New Jersey, and numerous others recorded of the same character, which terminated fatally after a few months, from leaving these irritants pent up to produce abscesses and compression, also bear testimony against the policy of non interference.

November 17, 1876.

THE BOGUS MEDICAL DIPLOMA traffic is quite brisk in France.

A CASE OF TETANUS SUCCESSFULLY TREATED BY CALABAR BEAN.

By FRANK S. GRANT, M.D.,

YONKERS, N. Y.

In an interesting communication from Lewis A. Stimson, M.D., on the "Treatment of Tetanus by Calabar Bean," which appeared in the last November number of the RECORD, the writer says: "As it is essential to the proper appreciation of the therapeutical value of the agent that the failures should be reported as well as the successes, I send you the following notes," etc.

Now, believing that many of the failures attending the administration of Calabar bean for tetanus have been due either to a poor preparation of the agent, or insufficient doses, or both combined, and having recalled to my mind, after reading Dr. Stimson's case, the successful treatment of a cure of tetanus by Calabar bean, I thought it might not be uninteresting to place it before the readers of the RECORD while yet the subject was fresh in their memories.

The following history is taken from notes, made while serving as house-surgeon to St. John's Hospital, Yonkers, N. Y.

Fritz Rannon, aged 21, single, native of Germany, admitted to hospital August 19, 1874. This man, while attending to a boiling vat of sugar, tripped and fell in up to his waist; he quickly got out, but was terribly burned by the boiling fluid. He was conveyed to the hospital soon after the accident. He improved slowly under appropriate treatment until September 12th, when the nurse reported that he had been very restless through the night, and sometimes excited.

September 13th. Restless, in a half sleeping condition, and with sudden fits of starting, as from a nightmare. It was also noticed he had occasional contractions of the platysma and facial muscles, with temporary fixation of the lower jaw. Later, he complained of sudden pains "shooting all through him." At night the muscles of the legs and abdomen underwent sudden and painful contractions. He was now, by order of the visiting surgeon, Dr. Pooley, given a prepared tincture of Calabar bean in ten drop doses, repeated every hour and gradually increased; also ordered beef-tea, wine, and milk frequently.

September 14th. Was delirious all night, the spasms have not increased; he now takes twenty-five drops of the tincture every hour.

September 15th. The tetanic spasms have not increased, but the patient's appearance is that of one worn out with fatigue and anxiety. The dose of the tincture was increased to thirty drops every hour, and the following prescription ordered:

℞. Chloral hydrat.,
Potass. bromid.....āā ʒi.
Aquæ ..... ʒiv.
M.
Sig.: A dessertspoonful every three hours.

September 16th. Has slept calmly nearly all day, and awoke towards night feeling much refreshed.

September 20th. Since the above date patient has improved slowly; tincture Calabar bean, in thirty drops, has been given three times a day, as symptoms of tetanus have subsided.

September 29th. While in the bath this morning patient was seized with a general spasm or opisthotonos, which lasted in bed fifteen minutes. A strong solution of Calabar bean was immediately made and administered as follows:

℞. Extract physostig ..... gr. xxxij.
Alcohol dil ..... ʒi.
M.
Sig.: Forty-five drops to be taken every two hours.

Towards the afternoon the spasms subsided in force and frequency.

October 1st. On the 30th, patient feeling very comfortable and no evidence of irritation, the dose of the bean was continued only three times a day. During this afternoon he was suddenly seized again with opisthotonos which lasted for nearly two hours. The dose was now increased to sixty gtts. every hour.

October 2d. Better; no return of spasms this morning; medicine continued in the same manner.

October 4th. Patient has been doing perfectly well; has lost the fatigued and anxious look; the dose of drug was reduced to thirty gtts. thrice daily. From this date until his convalescence the patient had no further return of tetanus. The drug was gradually given in smaller doses, and finally stopped altogether.

REMARKS.—There are a few chief features in the history of this case worth remarking upon. It will be observed that during the tetanic condition, whenever the drug was not pushed, the spasms returned with greater or less frequency, and that only when it was given in large and frequent doses (larger than in any case I have heard or read of) did its power become evident. The largest dose in Dr. Stimson's case did not exceed one and a half grains, and this when the symptoms were most severe; while in this case the maximum dose reached at one period four grains, and was continued for some time after the subsidence of marked spasms in three-grain doses.

No distinct physiological action of the agent was noticed during its administration, beyond contraction of the pupils and slight delirium at times.

The tincture which was first used, was prepared at the hospital by subjecting freshly crushed beans to the action of pure alcohol, and giving this as a saturated tincture; but the extract which was especially ordered came from the firm of W. H. Schieffelin & Co., New York.

107 WARBURTON AVE., YONKERS, N. Y.

A SUCCESSFUL CASE OF AMPUTATION OF THE THIGH TREATED ANTISEPTICALLY.

By LEWIS A. STIMSON, M.D.,

SURGEON TO PRESBYTERIAN HOSPITAL, NEW YORK

W——, 37 years old, was admitted to the Presbyterian Hospital 13th November, 1876, for a central osteo-sarcoma occupying the lower half of the left femur. Amputation was performed November 21st, as follows, Drs. Van Buren, Detmold, Keyes, and the resident staff of the hospital assisting: A medium-sized Lister's spray-producer, supplied with a five per cent. solution of carbolic acid, was so placed that its spray would fall directly upon the cut surface. The thigh was washed with a 2½ per cent. solution of carbolic acid, and the instruments placed in a basin filled with the same. The antero-posterior flap operation through the upper part of the middle third was performed, an Esmarch's band having been applied to the leg and a tourniquet to the femoral artery. The anterior flap, cut rather short on account of the proximity of the tumor, was made from without inwards, the posterior one by transfixion. The artery was found high up in the posterior flap, and a carbolized catgut ligature applied, both ends of which were

cut short. All other bleeding points, about fifteen in number, were secured in the same manner.

It had not been thought prudent to carry the elastic bandage over the tumor itself, and the flow of blood from the enlarged distal veins was therefore considerable; but the arterial supply was controlled so effectually by Dr. Van Buren, that little or no blood was lost from the upper side. The sciatic nerve was dissected out and cut off high up, so as to save it from becoming imbedded in the cicatrix in case primary union should not be obtained. A carbolized drainage tube, to provide for the ready escape of the first flow of serum, was placed across the bottom of the wound, and the edges of the latter then brought together with silk sutures prepared with carbolized beeswax (about 1 to 5). A strip of "protective" was laid along the wound, the end of the stump covered with a square piece of muslin dipped in the carbolic solution, and eight thicknesses of carbolized gauze prepared by Caswell and Hazard, but identical with that made in Edinburgh, placed over all and bound down with a roller bandage. A drachm of brandy was given hypodermically, and the patient placed in bed and surrounded with hot-water bottles.

The shock of the operation was considerable, and the temperature fell that evening below 97°; but the next day the patient had reacted finely, and since then he has eaten and slept better than for months previously, and has suffered no pain. Before the operation his general condition was bad, his appetite poor, his tongue red and glazed; his temperature rose from 1½ to 2½ degrees every afternoon, and the pain, especially at night, was very severe. The preparatory treatment consisted of careful nourishment and tonic doses of mercury, in accordance with the facts recently established by Dr. Keyes. During the first twelve days following the operation his temperature never rose above 99¾°; on the thirteenth day it rose to 100¼°, returning on the fifteenth to 98½°, an excursion due apparently to the appearance of a large carbuncle over the sacrum.

Two weeks after the operation, the entire wound had united by first intention, except at the outer angle, where the drainage tube had been maintained. No bare bone could be felt, and the sinus was not more than 1½ inches deep. All the sutures had been removed, and it is worthy of remark that, although some were left in place fourteen days, there was no suppuration about them. On the tenth day the patient was able to sit up, and on the fifteenth to walk with crutches.

The dressing was renewed the day after the operation and every second day thereafter for ten days, always under the spray, a frequency which was due to my desire to run no risks, and not to the amount of discharge, of which, if we except the first flow of serum, there has been scarcely half an ounce all told.

The tumor was presented to the Pathological Society November 22d, and a full description will be found in the report of the meeting in a future number of the MEDICAL RECORD.

I feel justified in calling attention to this case, because the rapidity of the recovery and the absence of all complications seem to have been due to the antiseptic treatment, and because, taken in connection with the good results obtained in two capital operations performed by Dr. Keyes (one of which was published in the RECORD, October 28th), and three minor amputations and one compound fracture of the tibia treated similarly by myself, it furnishes an additional reason why a method which has been cordially adopted and conscientiously practised in all its details for several years in England, France, and Germany, should no longer be a rarity in America.

The apparatus used on this occasion was loaned by Dr. Van Buren, who has been very active in calling the attention of the profession to the advantages of the method, especially as a means of settling some of the most important and perplexing nosocomial problems.

Progress of Medical Science.

LISTER'S SYSTEM AS USED AT FREIBURG.—Dr. A. W. C. Berns furnishes a summary of the results of the Lister treatment of wounds as obtained in the Freiburg clinique, under Prof. Czerny. In April, 1874, they adopted this treatment. In 1873, there were 901 cases treated, with forty-five deaths, of which nine were from pyæmia and three from erysipelas. In 1874, 910 cases and forty-two deaths, of which pyæmia claimed five and erysipelas three. In 1875, 864 cases and twenty-four deaths, three from pyæmia and one from erysipelas. Conservative surgical procedures have been notably benefited by the employment of this method. Dr. Berns concludes that, while the clinical material remained the same in quality, and other conditions were unchanged, the comparative mortality, and the incidental wound-diseases diminished, as a result of this mode of treatment, although, to be sure, the figures given are small.—*Archiv f. klin. Chirurg.*, XX. 1, 1876.

THE OPEN TREATMENT OF WOUNDS.—Dr. Burow, of Königsberg, reports the results of 123 operations performed by his father and himself during a period of nineteen years, and treated by the open method. The following are the figures given. There were 123 cases, with nine deaths, *i.e.*, 7⅓ per cent., comprising thirty-three amputations of the thigh with six deaths, or 18 per cent.; twenty-four amputations of the leg with three deaths, or 12 per cent.; and twenty-five amputations of the arm, twenty-nine of the forearm, nine of the foot, and two of the hand without any fatal case. These figures furnish a most interesting comparison with those compiled by Paul, Malgaigne, Ashhurst, and others, more especially Krönlein, Volkmann, and Thiersch. Dr. B. supports with sound arguments the character of his statistics, while acknowledging that the figures are small. He gives in brief the following as the essentials of the system he follows. In a case of amputation of the breast, he carefully checks the bleeding by the use of silk ligatures which he cuts off short. The wound is then left absolutely open, being protected from dust and flies by a simple oiled cloth. No sutures or plasters are used. When the first oiled cloth is loosened by suppuration, a second is applied dressed with a simple ointment. When granulations spring up luxuriantly, the cloth is wet with a solution of acetate of alumina. This is the whole treatment. After amputations of limbs, he first ligates the larger vessels before loosening the Esmarch's tube, completing the ligations after removing it. The wound is then left open for half an hour with the double object of guarding against secondary hemorrhage and of allowing the surface of the wound to ooze with a serous fluid. Then he puts in three sutures, securing them with a loop and not a knot, so as to allow for swelling of the tissues. Two or three strips of plaster are placed between the sutures, and the lower angle of the wound is left wide open for the free escape of discharges. Then by position of the limb and careful watching, it is made sure that the secretions can escape freely. He does a flap operation,

insists on the greatest cleanliness on all hands, and never uses sponges a second time.—*Archiv f. klin. Chirurg.*, XX. 1, 1876.

THE DIAGNOSIS OF DILATATION OF THE STOMACH.—Prof. W. Leube finds great uncertainty attending the diagnosis of certain diseases of the stomach, and turns his attention to data other than those associated with dyspepsia. In cases of dilatation of the stomach, the amount of matters vomited may be of diagnostic significance, if in excess of from five to eight pounds, the normal capacity of the organ. Neither visible peristaltic movements, nor audible splashing sounds when the body is shaken, are distinctive of dilatation of the stomach. Percussion aids him in the diagnosis of this condition, under favorable circumstances. There is dulness extending horizontally across from the arch of the ribs when the patient is erect, and this dulness is replaced by tympanitic resonance when he lies down. To determine whether this cavity is the stomach or a distended colon, Leube observes the percussion note, after the introduction of a considerable amount of fluid, either by swallowing or by using the stomach-tube, in which latter case it can be introduced and removed at pleasure. So after pouring in a litre of fluid, if the level of the fluid is not much higher than the navel there is dilatation of the stomach. The most convincing proof of dilatation, however, he finds in introducing a long bougie or tube into the stomach, and then judging of the degree of depression downward of the greater curvature by palpation through the abdominal wall.—*Deutsch. Archiv f. klin. Med.*, XV.; *Med-Chir. Rundschau*, 1876; *Allg. Med. Cent. Zeit.*, Oct. 28, 1876.

CHRONIC RHEUMATIC MYITIS.—Dr. Uno Helleday says that but little is known definitely with reference to the pathological anatomy of this disease.

As for the symptoms, pain occupies the first place, in the opinion of the patients and that of the greater part of the physicians. This symptom is uncertain and generally indefinite. At first its character varies considerably; it scarcely ever remains the same in different individuals, and changes in the same patient, even disappearing from time to time. It does not always correspond to the part which is in reality attacked; it may be entirely wanting, etc. It may also depend on numerous other diseases. It is not rare, however, that a true myitis gives rise to pain in parts which are quite distant from the seat of the disease. It is probable that there is then a compression, exerted by the smaller portions of the muscles on the nervous filaments, and the symptom exhibits itself at their peripherical ends.

The sensibility of the diseased point to pressure has no further value. It exists in several other diseases, and may be wanting in myitis.

The function of the diseased muscle is most frequently impaired, but one may be entirely mistaken concerning this during life. The impossibility of using the muscles freely may arise from other causes, and, on the other hand, the muscular groups, which seem to be paretic and are really so, sometimes present no traces of inflammation. The source of this is much further removed.

The external swelling of the affected muscles is most frequently minimal or nul. It is by palpation, carefully performed, that a diagnosis is made. It is not necessary that the volume of the diseased portion of the muscle should be augmented, although this happens often enough; the characteristic changes refer rather to the consistence, and, above all, to the muscular elasticity. This resembles that of the muscle in the condition of contraction, and the diseased points may attain an almost ligneous induration, although the author has never in reality found the diseased muscle contracted. The diseased foci—for the disease in question quite frequently presents itself under this form—are less easily displaced with regard to each other and the intermediate healthy parts. It is necessary to know, however, that the consistence is not always augmented; it may be found normal and even diminished, but the want of elasticity is constant. This is the pathognomonic sign, but to appreciate it a thorough knowledge and a careful examination are necessary.

The muscles are rarely affected in their totality. The seat of the disease is most frequently found near the attachments. Sometimes one feels numerous nodosities scattered through one or several muscles, the intermediate substance being healthy. The more advanced the anatomical changes are, the less the patients complain in general of the sensibility to the touch. The rheumatismal callosities are as a rule not painful.

The treatment should be directed by the rule that we must, first of all, endeavor to diminish the morbid production, by causing its absorption.

Massage is the best remedy, because it acts directly on the diseased points, and it has a more certain influence on the absorbent organs, than any other remedy, internal or external.

In recent cases its effect is often miraculous; but even in older cases of myitis, which have generally been previously treated by many other means without a durable advantage, it gives a good result, provided the cure has not been rendered impossible by the destruction of the muscular tissue. It is necessary to continue the treatment by massage, not only until the pains have ceased, and the patient has recovered the free use of his muscles and believes himself cured, but even to the time when he is really restored and the last trace of the disease has disappeared. In inveterate cases this requires much time. Eight cases are detailed, illustrating the difficulties of the diagnosis and the triumph of massage.—*Nordiskt Medicinskt Arkiv*, 8de. Bd., No. 8.

A NEW COLORING FLUID FOR HISTOLOGICAL USES.—Prof. Dreschfeld, of Manchester, recommends a watery solution of eosin in the proportion of 1 part to 1000 or 1500 of water, as possessing many advantages for coloring microscopic preparations. The thin section, either recent or hardened, requires to be placed in the fluid thus prepared, for not more than one minute or one minute and a half, and on removal is put for a few seconds in water weakly acidulated with acetic acid. The watery solution, so easily prepared and preserved, is one great advantage. A second one is the short time required for completely staining the tissues. In the third place, eosin renders the tissues clear and the histological details distinct. Fourthly, it differentiates the various tissues beautifully, a property which is very useful in examining the nervous tissues and compound tumors.—*Centralbl. f. d. Med. Wiss.*, Sept. 30, 1876.

EMPHYSEMA OF THE SKIN DURING PARTURITION. Dr. P. Alekschieff mentions, in the *Russisch Med. Rundschau*, Bd. 2, 1876, a rare complication of parturition which he observed at the obstetrical clinic of Moscow in a primipara, twenty-four years of age. During the application of forceps, rendered necessary by a contracted pelvis, a tumefaction of the skin of the neck was observed above the right clavicle, and this tumefaction increased largely during the uterine

contractions. There was observed an intumescence of the face, and especially of the palpebræ, the neck, and the upper portion of the thorax. This swelling constantly increased, and a manifest crepitation could be felt with the finger. Nothing particular could be perceived in the respiratory organs, except a certain weakness of the respiration of the right side. A live child was delivered with the forceps, and the emphysema disappeared in twelve days without any treatment. This case was due to the passage of air to the skin through lacerations of the pulmonary tissue, the result of intense muscular contractions.—*Lo Sperimentale*, August, 1876.

Poisoning by Œnanthe Crocata.—Dr. Foss relates nine cases of poisoning in children by this plant. The root was the portion eaten by the victims. It is said to have a sweet taste, which is soon followed by a sharp pungent sensation. The plant is called the five-fingered root, and is used very frequently in some parts as a dressing in severe cases of whitlow. The symptoms of the poisoning were similar in all the cases. Fifteen minutes after eating the root they all became unconscious, and had convulsions at intervals of half a minute between each. The pupils of the eye were widely dilated, the eyes were fixed and never moved, and the retinæ were insensible to light. There was no paralysis, reflex excitability, or any tendency to vomiting or purging. The pulse at the beginning of the attack in each was about 100, but for several hours before death was imperceptible. Post-mortem examination showed the left side of the heart to be filled with clotted blood, and the right side to be empty. Both lungs were congested, and upon section dark blood and frothy mucus oozed out. The blood-vessels of the membranes of the brain were congested with black blood, and so the substance of the cerebrum and cerebellum.—*The Practitioner*, October, 1876.

The Rôle of Granulation Tissue in Scrofula.—As early as 1865 Dr. Rubl had come to the conclusion that almost all scrofulous abscesses and ulcers were primarily due to the production of a tissue that closely resembled the granulation tissue, which Virchow had shown to be the foundation of syphilitic, lupous, and leprous growths. Continued observations of a very large number of cases have since then convinced him that almost all the diseased processes in scrofula depend on the production and development of granulation tissue. The characteristic peculiarity of this granulation tissue is that it contains all the forms of the elements of connective tissue, although the embryonic forms are most abundant. It consists mainly of lymphoid cells and of round or branched cells which resemble them, but are much larger; in addition to these there are numerous polynucleated cells, cells undergoing division, and cells in which endogenous cell-growth is taking place. The last are most frequently giant-cells, which are a constant and often a very large constituent of scrofulous granulation tissue. These are in part developed from lymphoid cells, but in part from connective-tissue corpuscles, endothelial cells, or bone cells, which have been excited to proliferation by an inflammatory irritation. Some of them by absorption of protoplasm, and others by union with other cells of the same sort, attain an immense size. When their development is completed, they break up into lymphoid or rather epithelioid cells, which also possess the faculty of proliferation. Besides these cells, the granulation tissue contains spindle cells in various stages of development, and elastic fibres which are partly the remains of the tissue that was replaced by the granulation tissue, and partly a new formation. In the latter case they often resemble embryonic fibres, and their connection with spindle cells can be easily demonstrated. Finally, blood-vessels which are partly of new formation may also be present. This granulation tissue consequently is distinguished from the normal tissue especially by the number of large cells, rich in protoplasm, which it contains. It consists of a collection of these brood-cells, simply lymphoid corpuscles, and young embryonic elements of different forms, which possess the characters of an inflammatory growth.

This granulation tissue may finally undergo a caseous metamorphosis, or it may be organized in the usual way and remain a permanent constituent of the body. In the former case, the product of degeneration may be semi-purulent, or thicker and pap-like, or may be firm and hard as a potato. Microscopically it then consists of bright granules, separate and in masses, of free nuclei, of pus cells, and of other cells of varying size and form, some of which have undergone amyloid degeneration, and some are still well preserved. Well preserved cells are found even in very old cheesy collections. This granulation tissue may start from the connective-tissue cells as well as from the lymph cells. Most frequently, in consequence of a local obstruction to the flow of lymph, some of its cells are placed in abnormal conditions of existence, and then take on the above-mentioned changes through proliferation. When some of these altered cells are carried to distant parts through the interstitial lymph canals, they may excite similar processes there. The phthisical process in the lung and other internal organs is in every respect the same as the scrofulous inflammation of external parts. The anatomical changes, the course, and even the mode of cure, are the same in both. Phthisis is one of the forms in which scrofula may and often does appear.—*Centralblatt für Med. Wissen.*, September 9th.

Cinchona Cultivation in India.—We learn from the recently published report of the progress and condition of India that the cultivation of the bark is very successful in most of the districts where it has been planted. In Sikkim there are now nearly three millions of trees in growth, a large proportion of which are the red variety, yielding a large quantity of alkaloid. The statement that "the inquiries of the Government quinologist have resulted in a cheap and efficient method of extracting the febrifugal alkaloids from cinchona bark" must interest all the manufacturers of quinine at home. In the Neilgherry Hills there are about 3,000 acres under cultivation, most of which are private plantations. The manufacture of amorphous quinine having ceased in August, 1875, all the bark is now dispatched to the London market for sale. In Bombay it has been decided, after a trial of ten years, to abandon the attempt to grow the plant on the Mahableshwar Hill, the climate being unsuitable. In Mysore there are two plantations, the bark being of a somewhat inferior quality, yet efficient in checking ordinary attacks of intermittent fever. In British Burmah the cultivation of the bark is carried on with success. The Indian Government, however, has decided not to manufacture quinine in this province.—*Lancet.*

Scarlatinal Dropsy.—Dr. S. D. Bell (Trans. Med. Soc. *Penn.*) claims great success in the treatment of this complication, by the use of a decoction of scoparius, prepared by boiling half an ounce of the tops in a pint and a half of water down to one pint. Dose, tablespoonful to wineglassful every four or six hours.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 16, 1876.

THE METRIC SYSTEM IN PRESCRIPTIONS.

In our last we considered the manner in which fluid preparations are dispensed by apothecaries, and will now invite attention to the Troy weights in use among them.

Referring to the price list of a prominent firm, we find that they offer for sale a set of weights, consisting of thirty-five pieces, for thirty-eight cents (rather cheap to be very good); and a set of grain weights, four pieces for ten cents. A set of these latter being tested gave the following results:

Nominal weight.	Actual weight.
¼ grain.	.35 grains.
½ "	.90 "
1 "	1.10 "
2 "	2. "

It will be seen that of these four, but one was correct, and that the others were respectively ten per cent., forty per cent., and eighty per cent. over weight. These weights were of German manufacture.

Another set (American make), consisting of thirteen pieces, and sold for twenty-five cents, were found to be reasonably accurate, the error in none exceeding two per cent.; but a set of grain weights (same make) comprising seven pieces for nine cents, was vitiated by the one-half grain piece, which was found to weigh .29 gr., or a little over a quarter of a grain. Our next researches were at the shop of an apothecary, who permitted us to test his weights, and among which we found the following:

Nominal weight.	Actual weight.
3 grains.	2.75
4 "	2.73
5 "	3.80
6 "	4.43
480 "	458.85

At another store eight or nine small weights were examined, with the following result:

Nominal weight.	Actual weight.
3 grains.	3.15
4 "	4.35
6 "	5.10

At this store we also found a small German saddle-scale, graduated from .1 gr. to 5 gr., in which the arm carrying the saddle was .2 gr. lighter than it should have been; consequently, if half a grain of morphine had been ordered, .3 gr. only would have been furnished, or if .3 gr. were ordered .1 gr. only would have been weighed. At a third store we found everything as it should be; but at a fourth, the proprietor declined to permit us to examine his weights. He said that he knew they were all right, because he had used them for several years. The two shops we first visited, and in which the defective weights were found, are situated in prominent thoroughfares, and enjoy first-class patronage. These few examples are of course not conclusive, but they permit a fair inference that a large proportion of the prescription weights used in this country are inaccurate, and many of them seriously so. We have made inquiry of several apothecaries as to whether their weights were regularly examined by the Inspector of Weights. The uniform reply has been, that their avoirdupois weights were inspected, but that their prescription weights were not. We see, then, that if we buy a pound of bird-seed, there is every prospect of our getting accurate weight, but with strychnine or atropine the case may be very different. We have been further assured by an apothecary that, in a prominent store in which he was once a clerk, there was not a balance in the establishment that would turn with less than three grains, and that it was the custom to *estimate* all smaller quantities. Another apothecary states that he knows of a store in which there are no Troy weights over half an ounce, all weighing above that amount being done with avoirdupois.

These facts, and those which we stated in our last concerning the indifferent use of the fluidounce and the Troy ounce, certainly lead us to believe that some change from present customs is desirable.

The practice of medicine necessarily presents so many uncertainties, that we should make an effort if possible to diminish them; and if we can secure uniformity in the dispensation of our medicines, we can thus eliminate at least one variable factor.

The abolition of *measures* of *capacity* in pharmacy, and the dispensation of all medicines (solid or fluid) by weight, is, we think, a step that will meet with acquiescence from all those who have given much thought to the matter. It is the practice in every country in continental Europe, and would now be the custom here if the committee who revised the Pharmacopœia had not been too lazy to perform the duties assigned them by the National Convention of 1870.

We should also make an effort to secure a reasonable degree of accuracy in all weights employed in

pharmacy; and we believe that we are not over-fastidious in demanding that the smaller weights shall not vary more than one per cent. from the standard, and that the larger ones shall vary still less. As it is perfectly practicable to detect a difference between weights of one-hundredth milligramme, that is, less than one-five-thousandth of a grain, we feel that we have a right to demand of the apothecary a decent approximation to the standard. The necessity of a change being conceded, in our own mind at least, brings us to the consideration of the question, as to whether it would be better to employ the metric, or whether we should make an effort to perfect our present system. The discussion of this point we leave until our next issue.

TYPHOID FEVER IN PARIS.

THE leading article in the last number of La France Médicale contains interesting points as to an epidemic of typhoid fever now raging in Paris. The Administration of Public Assistance has provided a special hospital, and the general hospitals have an unusual number of cases.

During the last three months the number of deaths has been more than double that of the preceding four years. According to the figures of M. E. Bernier, who is charged with the duty of reporting upon prevailing diseases, the number of typhoid-fever cases for the third quarter of these preceding years has been three hundred and sixty-three, of whom ninety-three died, making a mortality of twenty-five per cent. Now, for the corresponding quarter of the current year the records of hospitals give seven hundred and fourteen cases, which are double those of other years, and the mortality has been thirty-five per cent. instead of twenty-five. In the two preceding quarters the average of deaths was twenty per cent.

The fever exists permanently in Paris, and each autumn it undergoes a constant and considerable exacerbation, varying in degree, but regular in its return. This year it is coincident with unusual atmospheric conditions. M. Bernier has studied with zeal the course of the epidemic in the various arrondissements (wards) of Paris. He has found that the influence of population, that of altitude, poverty, or wealth, do not furnish data for conclusions. The epidemic is also remarkable in other features than its number. There is noted an especial severity of the early symptoms. The invasion is insidious and rapid. Several hospital physicians have noticed an absence of diarrhœa and epistaxis, and the early appearance of the eruption of spots. At the present time it assumes an adynamic form. A further point observed by M. Bernier is that there is a seemingly increased power of contagion.

The Assistance Publique has opened a temporary hospital. The mortality last week was one hundred and seventy-one, while the week previous it was fifty-nine.

MEDICAL PATENTS.

A CORRESPONDENT, commenting upon the account given by our Philadelphia correspondent concerning the wonderful exhibition of skill and ingenuity on the part of the instrument-makers at the late Centennial Exhibition, very pertinently asks, whence comes the "skill and ingenuity?"

Claiming, as he has a right to do, that in the vast majority of instances the medical profession deserve the credit for these inventions, he opens the question of medical patents by the following pertinent remarks:

"It may not be out of place to ask, What means will best secure a pecuniary return to medical men for their designs and inventions?" Scarcely a day elapses without a new design being furnished to an instrument-maker, for the making of which he takes good care to charge a round sum to the designer, and then he manufactures and sells the article at an immense profit to himself. Could not some arrangement be made with the trade, to allow the profession a *royalty* on all designs and inventions accepted, manufactured and sold, leaving to the former the sole right and privilege of *patenting* and selling? This plan would save the dignity of the profession, and though not so remunerative as the holding of a patent, it would nevertheless give a physician some pecuniary recompense for the outlay of his time and means, and for the labor of his brain."

CREMATION AS A SCIENCE.

DESPITE the recent effort to popularize cremation by the final disposal of a famous corpse, the public are as much, if not more inclined to old-fashioned burial than ever. In fact, as the result of the recent exhibition in Pennsylvania, cremation as a science has lost ground. The furnace, as exhibited on the occasion to which we refer, was a very complete one of its kind, and its construction was based upon strictly scientific principles—in fact, it accomplished everything anticipated. So far as the corpse was concerned, everything went off satisfactorily, but whether other corpses are likely to follow the example is a question. It is a pity, however, that such a perfect furnace should not be turned to some more useful purpose.

FIRES IN THEATRES.

THE recent terrible catastrophe at the Brooklyn Theatre has aroused public concern regarding the best means to be adopted to guard against the effects of fire in large and crowded buildings. It is of course useless to attempt to control any crowd when under the maniacal influences of a panic. The safety of the great majority composing it rests altogether upon prevention. Obviously the best assurances in this direction are the greatest possible facilities for rapid egress and the prevention of the spread of the flames from

one part of the building to the other. In regard to these points, very few, if any of the public buildings of this city are absolutely safe. In our theatres, with one or two exceptions, no extra provisions are made against the occurrence of a panic, and no extra precautions taken to arrest the progress of a fire among the scenery. In the case of the Brooklyn Theatre, all the necessary conditions were present beforehand to bring about the terrible results which have so recently shocked the community. Dreadful as is this experience, resulting from inefficient preparations, some good may yet come of it in the way of a demand from the authorities, and from the public, for security in the future. Of the numerous suggestions which have been made, those referring to the control of fire have not only a practical, but a scientific interest to the medical profession. It is well known that by the aid of chemistry, all fabrics, whether for costume or scenery, can be made absolutely uninflammable. Not long ago the English medical journals, in commenting upon the death of two actresses by fire, discussed the subject of non-inflammable dresses in all its bearings, and advised that gauze and similar fabrics used by ballet-girls should be soaked in solutions of alum, or in some of the silicate salts. This suggestion has been adopted in some of the London theatres with good results. Although this precaution in regard to the dresses of actresses would not have prevented the Brooklyn disaster, it would certainly have its good effect if the "flies" of the scenery had been made non-combustible.

The President of the Board of Health, Professor Chandler, has very properly, it seems to us, advised that the scenes be painted in water colors and coated with a solution of silicate of soda. These precautions, together with those suggested by others, in regard to the free supply of water-pipes among the scenes, an iron curtain to shut off the fire from the audience, and a trained fire brigade attached to each place of amusement, are all thoroughly practical, and we are in hopes that popular opinion will prepare the way for their ultimate adoption.

Walsh's Physicians' Combined Call Book and Tablet.—This visiting list is arranged in a most convenient form for the pocket, and, in this respect, we think that it is superior to any other which we have seen. It is bound in leather, is seven and three quarters of an inch long, four wide, but *three-eighths* thick, and is interleaved. It is so arranged without dates as to be good for any year, or any time in the year, and can consequently be used until filled. It enables the physician to write the name, address, and number of visits paid each patient (thirty-five per week) on one page and line, and by using additional pages, the list may be extended as desired. A convenient and novel feature is an *erasable tablet* bound on the inside of the front cover, upon which memoranda may be written. The publisher is Ralph Walsh, M.D., 227 Four-and-a-half street, Washington, D. C.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 8, 1876.

Dr. C. K. Bridion, President, in the Chair.

(Concluded from page 804.)

WATERMELON-SEED IN TRACHEA—TRACHEOTOMY.

Dr. Erskine Mason presented a watermelon-seed which he had removed by tracheotomy from a boy six years of age—a patient of Dr. Horton, of Morrisania. He was called to see the patient, Aug. 5th, and found that four days before, while eating watermelon, he had swallowed a seed that had passed into the trachea. He had suffered from cough since the occurrence of the accident, and on the night previous to the doctor's visit had had an attack of dyspnœa. When first seen, Aug. 5th, the boy's voice was husky, and the foreign body was readily detected in the trachea by auscultation when the patient coughed. The trachea was opened below the isthmus, and as soon as the opening was made, something flew out and struck the doctor upon the cheek. It was supposed to be the seed that had been swallowed, but upon the most diligent search no seed could be found. The patient, however, at once began to breathe more quietly. A tube was introduced, a pair of curved forceps passed through, but nothing was clutched. The tube was allowed to remain until two days after, the breathing being quiet, when it was removed. A slight amount of bronchitis was present. Aug. 14th, nine days after the operation, Dr. M. was sent for, and found that the boy had done well up to the previous night, when he had a terrible paroxysm of coughing like those which had previously occurred, and which lasted from 12 to 3 A.M. Dr. Horton informed Dr. M. that up to the morning of the 14th it could not be determined that any air entered the right lung, and yet there was no dulness upon percussion; nor was there any increased frequency of pulse or elevation of temperature. When Dr. M. saw him at 4 P.M., air was entering both lungs freely, and on coughing a foreign body could be detected in the trachea. The boy was placed under the influence of ether, and the original opening dilated by means of an instrument, and as soon as the dilatation was sufficiently complete, a violent paroxysm of coughing ensued, and the seed was expelled. The wound healed rapidly, and the following Sunday the boy went to Sunday-school.

The case was interesting in two particulars:

1. The seed remained in the boy's trachea thirteen days.

2. It illustrated how easily the surgeon might be deceived with regard to foreign bodies passing out after an opening into the trachea had been made.

CANCER OF THE STOMACH.

Dr. John C. Peters presented a cancer of the stomach, in which perforation of the coats of the organ would probably have been complete had it not been for an enlargement of the liver.

The patient was a man, 53 years of age, who lived somewhat well, and was perfectly healthy up to two years before his death, at which time he began to suffer from dyspeptic symptoms and more or less mental depression regarding the rapid approach of death. He was repeatedly examined; enlargement of the liver was detected, there was a fulness and a board-like

hardness across the epigastrium, but at no time was any tumor detected. Dr. Loomis saw the man, but was also unable to detect any tumor. The man never had vomiting, but complained of suffering extremely after the least imprudence in diet, and anything more than a small quantity of bland food was taken. His case had been regarded by one physician as one of neuralgia of the stomach, proceeding from malaria. Inasmuch as he had not had malarial manifestation, and no pain whatever except from imprudence in diet, Dr. Peters persisted in the opinion that there was present some organic disease of the stomach, probably of a cancerous character. All hereditary tendency to cancer was denied during life, but after death it was found that two or three of the members of his family had died of cancer of the stomach. The treatment was palliative, and the remedy which gave him most relief was hydrate of chloral. Administered in thirty grain doses at night and twenty-grain doses in the morning, the remedy kept him in a very comfortable condition. Shortly after taking the chloral one night he arose for some purpose, and, endeavoring to go about in a dark room, he fell and struck his head against a solid body, and died with all the symptoms of concussion of the brain.

The entire absence of vomiting and tumor throughout the duration of the disease were the interesting features of the case.

Dr. Loomis remarked that there was not present in Dr. Peters' case any of the so-called cancerous cachexia, and that neither primary nor secondary tumor of any kind could be detected. On palpation there was a feel as though there was a thickening of the tissues in the region of the stomach, and he was led to believe that the sensation was due to a thickened condition of the walls of the stomach, either malignant or non-malignant. In absence of all the ordinary symptoms and history of cancer of that organ, he was led to believe that some other condition was present.

Dr. Heitzmann remarked that he had made a microscopical examination of the specimen presented by Dr. Peters, and that he had found it to be cancerous in nature, and of the colloid variety. He further remarked that cancer of the stomach was not usually accompanied with secondary changes in other organs, but simply with swelling of the lymphatic glands, as was present in that case.

Dr. Sell presented a blighted ovum that had been cast off in the tenth week of pregnancy. It was thrown off, and the day subsequent was brought to the doctor at the Dispensary by the woman herself. She had had one living child, and had aborted three times. In the first two abortions she was sick with labor pains and progressive hemorrhage, and then the ovum was cast off. In the present instance, the ovum was discharged without pain or hemorrhage, and no discharge followed. The query was with reference to the cause of the abortion.

URETHRAL CALCULUS—DISCHARGE THROUGH AN OPENING IN URETHRA.

The President, in behalf of Dr. Stephen J. Clark, presented a urinary calculus one-quarter of an inch in its transverse, and one-third of an inch in its long diameter. Dr. Clark furnished the following history:

October 6th.—I was requested to visit a boy, three years old, who was suffering from retention of urine. On examining I found a congenital phymosis, and a scrotum enlarged to about three times its normal dimensions. After relieving the contraction of the prepuce by circumcision, I emptied the bladder with a No. 4 catheter, of about twelve ounces of urine; the distention was followed by temporary atony that required the use of the catheter for three or four days.

During the first week of my attendance upon him, an opening formed at the peno scrotal angle, that discharged about three ounces of fetid pus. I enlarged this opening to the extent of about two inches, and came in contact with a concretion situate in the depth of the wound under the pubic arch. It was my opinion at the time that the calculus had been impacted in the membranous urethra; that ulceration and perforation had allowed it to escape into the tissues outside; and that the channel through which it had escaped had almost immediately closed, for there was at no subsequent period the slightest escape of urine from the sinus through which the calculus was removed.

Dr. Satterthwaite, from the microscopical committee, made a report upon the tumor presented by Dr. Allin at the last meeting of the Society. It was found to be made mostly of spindle-shaped cells; there was also present a large number of round cells. The tumor was regarded as a periosteal sarcoma of the spindle-celled variety. Its malignancy was undoubted.

The Society then went into Executive Session.

NEW YORK ACADEMY OF MEDICINE.

OBSTETRIC SECTION.

Stated Meeting, Nov. 20, 1876.

Dr. Isaac E. Taylor, Chairman.

PLACENTA PRÆVIA: ITS PHYSIOLOGY AND ITS MANAGEMENT.

The Chairman laid before the Section the views which he had long held regarding the physiology and management of central implantation of the placenta. Fortunately, it was a rare occurrence. The location of the placenta, and how it came to occupy the position in which it was sometimes found, were questions that received special consideration. His remarks were based upon the following history of a case which had lately fallen under his observation:

A lady, æt. 34 years, Cuban, and the mother of five children, had been confined to her bed since June with malarial gastralgia. Distinct paroxysms of pain occurred at about two o'clock in the morning and at about the same hour in the afternoon. She became considerably enfeebled, although resolute, and at one time marked symptoms of peritonitis were developed, which subsided under the use of appropriate remedies. Her time for delivery was about the 20th or 25th of October. Dr. Taylor was called to visit the patient on the 25th of October, and found that she was suffering from considerable pain at intervals of fifteen or twenty minutes, without decided contraction of the uterus. There had been a slight show, but no hemorrhage. The pains became irregular, and after a time ceased.

On the 26th the pains were a little more active, yet there were no decided contractions of the uterus, and no hemorrhage. The cervix was long, and no distinct presenting part could be made out by vaginal examination. By external examination it became evident that there was a lateral presentation, and the fœtal heart was found to be acting well. On the 27th nothing special occurred. On the 28th a visit was made at about five o'clock in the afternoon, when it was found that she was having distinct uterine contractions—not a painless form of contraction, as some have supposed. There was, however, nothing specially urgent in the case, and the doctor left for home within a short time.

He had, however, scarcely reached there when he received a message to return as quickly as possible, on account of the occurrence of severe flooding. It seemed that the patient, from sitting in a chair, had attempted to rise and go to her bed, when the slight show increased to a rapid loss of blood, and she suddenly lost fully one quart. The appearance of the countenance indicated severe loss of blood. A vaginal examination was made immediately upon arrival, and the neck of the uterus was found open sufficient to admit two fingers, which were passed in an inch or an inch and a half, and a placenta was distinctly felt. The vagina was tamponed with a large sponge, and consultative assistance at once called. As soon as such assistance arrived, the woman was placed under the influence of chloroform, and version was performed by a combination of external and internal manipulation, only two fingers being introduced into the uterus. The placenta was separated over a small space, the fingers were passed up, and, by assistance from above—the uterus being pressed downwards—made to rupture the membranes, when version was completed. The child was perfectly bloodless. The pulse of the mother after the operation was rapid, and the respiration rather quick; but she ultimately did well.

The case was interesting because it illustrated so well the views Dr. Taylor had long entertained regarding the physiology and the management of placenta prævia, and which were so markedly at variance with those held by Barnes, Playfair, Schroeder, and others.

The views entertained by Dr. Taylor were that there was *no shortening* of the neck of the cervix during pregnancy; that the placenta, in cases of central implantation, was attached to the uterus at the *internal* os, and when found in the cervical zone, it was there because it had been driven down by the head of the child. The Doctor maintained that he had repeatedly demonstrated the correctness of these views by the introduction of a cylindrical speculum two and a half or three inches in diameter, during labor (a procedure that could be easily accomplished with multiparous women, in whom the central placental presentation occurred most frequently), and observing what was taking place. He had seen and the classes to which he had given the opportunity had also been able to see, the cervix open and close as uterine contractions came and went, as well as the exact spot where the blood came from. He had also been able to demonstrate, in the same manner and with the greatest certainty, that the placenta was not at the os tincæ at all until it had been brought there by the pressure produced by the descent of the child's head when presenting.

The head of the child, being in contact with the placenta, drove it down, when a uterine contraction took place, and when the contraction ceased the head receded, and with it the placenta. It was the gradual crowding down that separated the placenta directly from the body of the uterus, where it was originally attached; and when found at the os tincæ, in the cervical zone, it was there because it had been pushed there. The validity of that view was supported by the fact that when the Doctor visited his patient on the 26th, *the period beyond full term*, the cervix was found to be long, and no presenting part could be made out by vaginal examination. On the 28th, however, he found that uterine contractions were distinct, and that a placenta could be readily touched after passing through a cervical canal an inch or an inch and a half in length. Dr. Taylor maintained that the placenta in complete presentation was over the os internum; that the os internum, and not the os tincæ, as shown by Barnes, Cazeaux, and others, was the first to yield when labor began; hence the hemorrhage came from the centre.

Reference was made to the older view in accordance with which it was supposed that the hemorrhage was due to shortening of the neck, which began about the sixth or seventh month and gradually went on until at term the cervix had completely disappeared.

The next view was that entertained by Cazeaux, in accordance with which it was supposed that the lower portion of the uterus, during the last three months of pregnancy, underwent a special growth, and the placenta having obtained its full size, that that growth was the cause of the separation of the placenta from its attachments. Barnes's view was, that the detatchment of the placenta arises from an excess of growth of the placenta over that of the cervix, and adapted itself to the expansion of the cervix during the latter part of pregnancy. It was maintained that Dr. Barnes's diagrams, and one taken from Hunter, showing the safe placental attachment; the attachment in partial presentation, also safe; and the cervical zone, which was the unsafe, or the hemorrhagic zone, certainly set aside the view of non-shortening of the cervix, and in that contradicted the statements made by the author in the text of his book.

Playfair adopted the views of Barnes and Duncan, and claimed that about two weeks previous to labor painless contraction occurred which had a tendency to expand the cervix; the internal os gradually yielding until at the term of labor the uterus presented a perfectly oval form. From all those views Dr. Taylor dissented, and contended that the internal os remained intact throughout utero-gestation, and if a placenta was attached over it, that it also remained undisturbed until labor commenced. He had not only substantiated his views by direct observation during the progress of labor, but by post-mortem examinations in which the placenta had been found in the body of the uterus, although death had occurred from hemorrhage, and not in the neck at all. It is impossible for the placenta to grow in the cervix, and that it was necessarily attached to the body of the uterus. The uterus remained hermetically sealed until some cause brought on uterine contraction, such as a blow, a shock, a mental emotion, etc., and then labor commenced. Again, at full term, the pains began; contraction went on gradually expanding the cervix, whether placenta was there or not, the expansion beginning at the internal os; but suppose the placenta attached over that point, the result would be that it would be separated from the internal orifice before it was separated from any other portion of the uterus; the pains went on, slight hemorrhage occurred; the pains continued, the placenta became separated more and more, and the hemorrhage increased as a matter of course. If the external os was opened the size of a shilling piece, it was evidence that it had been separated probably to two-thirds the size of the child's head, and at any moment profuse hemorrhage might occur. Under such circumstances, Dr. Taylor proceeded to deliver the woman at once. There was no advantage in tamponing the vagina according to the older view, and waiting for farther expansion of the cervix.

Where the placenta could be felt in the cervical zone, the labor had placed it there; Barnes had not separated it as he believed; Nature had asserted her power and pushed the placenta down before the presenting part. What was the physician to do then? If the placenta was 5 inches in diameter, and the diameter of the child's head 3½ inches, it only remained to separate the placenta ¾ of an inch; if 6 in. in diameter and the head 4 in. in diameter, the

placenta remained attached only for a distance of an inch on each side; and now all that was necessary was to pass the finger up, separate the attachments at some point, rupture the membranes, perform bimanual version, and deliver if the child is malplaced.

Dr. Taylor had demonstrated his views repeatedly since 1852, although his first publication was in 1862.

Dr. Hubbard agreed with the chairman in the statement that central placental presentation was rare, having met it only three times in three thousand cases. He referred to one case in which the placenta was thrown into the bed by a uterine contraction,—the labor proceeded without farther trouble, and the woman was safely delivered. In a third case the placenta could be distinctly felt, was separated all around and removed, the hemorrhage at once ceased, and the labor went on in a natural manner.

Dr. H. then asked the question, why not proceed in that manner when the head or breech presented, and the child was either dead or there was no prospect of saving its life by version, instead of resorting to version as a general method of management?

Was not the woman subjected to greater risks, under such circumstances, by resorting to version than by proceeding as indicated?

The Chairman believed it unnecessary to separate the placenta completely, unless in an exhausted condition, and that a partial separation sufficient to permit of the rupture of the membranes was sufficient, as the operation of version could then be easily completed.

If the case was first seen when the os was nearly or completely dilated, it would probably be better to separate the edges of the placenta remaining attached, remove it, and let the case alone. The separation under such circumstances could be readily done. He did not deem it wise to permit the case to go until such a period was reached, and believed it to be the safer plan for the mother and child, as soon as the cervix was open as large as a shilling piece, to separate the placental attachments sufficient to permit rupture of the membranes and then complete the version by external and internal manipulation. If the head or breech presented, give ergot, separate the membranes, and let Nature deliver.

After the relation of several cases by different members, the Section adjourned. Immediately after the adjournment the Section was handsomely entertained by Dr. W. C. Livingston.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, November 17, 1876.

Dr. D. B. St. John Roosa, Vice-President, in the Chair.

EFFECTS OF LESIONS OF THE BRAIN UPON THE VISCERA, AND OF DISEASES OF THE VISCERA UPON THE BRAIN.

Dr. Eugene Dupuy remarked upon the above subject as follows:

Mr. President, Gentlemen—Notwithstanding the almost innumerable cases of diseases of the brain where autopsy always discovered lesions of a grave nature in the lungs, it is not more than six years ago that attention has been called to this most interesting point of pathology by my friend, Brown-Séquard. He showed that lesions experimentally produced in the base of the brain in guinea-pigs almost invariably give rise to hemorrhage in the lungs, in the heart, the stomach, the supra-renal capsules, the kidneys, the liver, and to congestion of the intestines. Except a few observations scattered in French and English periodicals, there is no mention to be found of these facts which are of such great importance for a correct prognosis and rational treatment of cerebral hemorrhage. Every one knows that in the majority of cases these hemorrhages are not fatal *per se*. Although I speak more particularly of cerebral hemorrhage, I shall comprise under such heading all diseases of the brain, such as tumors, abscess, fractures of cranium, inflammation of part of a lobe or of several parts, etc.

The facts which experiment has disclosed, bearing on the lungs, for instance, are the most interesting perhaps, because of the serious nature of a hemorrhage in lobes of the lungs, following and caused by an affection of the cerebrum. Œdematous patches of the lung tissue, sub-pleural large ecchymotic suffusion of blood, congestion of the lungs, are the usual consecutive lesions in the chest. The relation between the lung lesion and one in the cerebrum is so close in the human species, that Professor Ollivier, of Paris, has reported three cases of apoplexy, which he called pulmonary unilateral apoplexy, in which he found at the autopsies that with a hemorrhage in the left corpus striatum, having caused a right hemiplegia, there was congestion and apoplexy of the right lung. If you examine with care all the patients who may come under your notice, I am confident that you will always detect some trouble in the lung or the pleura of the same side with the palsied arm, and sometimes of both sides. The production of those alterations does take place very rapidly after the onset of the cerebral lesion, as it is an effect of it. While Dr. Brown-Séquard made his experiments on the subject, I being his assistant, then I could see the lesion in the lung take place under my very eyes, as the first lesion was being produced in the cerebrum.

The heart, in a less degree of frequency, is found to contain hemorrhagic spots after brain lesion. In animals the frequency is great enough, but not so in men. There is another morbid phenomenon produced by brain disease in human pathology: it is a state of the heart which so much resembles hypertrophy as to lead the inexperienced to commit an error in diagnosis. I believe that most of the patients who die of cerebral hemorrhage have that pseudo-hypertrophy of the heart, which, in its turn, is accompanied by dropsy. Such an opinion is strongly supported by the researches of Bouillard, Niemeyer, and others, who teach that that symptom never depends upon pure hypertrophy, but upon a weakening of the circulatory functions. Hence, Bouillard found by clinical accuracy what very recent researches in the physiology of the brain have proved.

On the kidneys the effects of brain lesions also manifest themselves in the shape of hemorrhage, congestion, etc. Ollivier has also shown that in human pathology cerebral hemorrhage gives rise to albumen in the urine within a very short time after the onset of the attack — sometimes, however, a long time after, but always at some period before death. Now this point must be understood in practice, in order not to commit errors in prognosis and treatment. In some cases albumen appears and disappears. The first case that came under my notice was in this very city, where I was visiting Dr. B.-S. some four years ago. A patient of his had been taken with palsy from hemorrhage on the brain; besides symptoms in the lungs and heart, his urine, which was examined by a physician of this city, was found to contain, two days after the attack, a quantity of albumen. I had examined the urine on the very day of the at-

tack, and it contained none then. It disappeared after the fourth day, and only reappeared some time before death, which followed in the train of large bed-sores.

Now, in regard to the correspondence of these lesions with particular parts of the brain, I have made quite a number of experiments within the last six years on these particular points and many others, and I think that I can safely say that any kind of lesion seated in any part of the brain, and even of the meninges, will produce in animals such symptoms, and the same is the case in the human subject, as I have found by analyzing an immense number of cases reported for other purposes.

But this is not all. Experimentation and clinical researches show that disorders of the viscera, thoracic and abdominal, also in their turn give rise to symptoms of lesions of the brain. My learned friend, Dr. Lépine, of Paris, has published a very excellent paper some six years ago, in which he has shown, supported by cases, that pneumonia does give rise to hemiplegia. He has very carefully collected his cases from the wards of Prof. Charcot and others, and his researches tend to show the connection between pneumonia and hemiplegia to be such that there is no room for supposing that in these cases there was only coincidence. Brown-Séquard has shown that lesion of the first thoracic sympathetic ganglion in guinea-pigs brings on vascular troubles in the ear and eye on the same side, rotatory movements, etc. Lépine himself has shown that injections of irritative substances in the lung tissue do cause constriction of the pupil on the same side, secretion of tears, etc. I have found that instilling a drop of absolute alcohol by the hypodermic syringe in the lung-tissue of a guinea-pig will give rise to transient paralysis of the anterior leg on the same side. Lately, Prof. Leudet, a most accurate observer, has reported that he has seen hemiplegia occur in a patient every time that he washed the pleural sac, from which he had aspired a quantity of effused matter. Such examples are not infrequently found when looking up cases in records, journals, etc.

The irritations of the liver in rabbits cause trouble of the innervation, which I doubt not have their parallel in human pathology. Those of the stomach are already too much known to require notice; let me say, however, that I have quite frequently seen the phenomena which Brown-Séquard has been, with Schiff, the first to notice. I mean the influence in animals exercised by lesions of the brain on the stomach. Physicians are well aware that a great majority of cerebral troubles originate in gastric disturbances; but I believe—and some few cases that have occurred to me in practice prove—that inflammation, or disorder of the brain of any kind, or of the meninges, are the most prolific producers of gastric disturbances—lesions of the intestines. I know that those physicians who devote special attention to diseases of children have noticed that sometimes disorders of the alimentary canal are found associated, in such a way as to suggest the relation of cause to effect, with inflammation of the middle ear. J. Frank, the learned pathologist, has indeed put on record that in man grave diseases of the liver do give rise to inflammation of the right ear. Now, gentlemen, I feel that I ought to explain here. There are practitioners who believe that the ophthalmoscope is the infallible detective of lesions of the brain. Some think even that they can localize the seat of the disease. In bringing to your notice that fact of possible connection between the liver disorder and the middle right ear inflammation, I do not intend to be credited with urging the use of the auriscope in order to discover the possible connection between the simultaneous disorders of the organs, and still less to locate anything in the brain, if there be also brain symptoms.

Experiments have taught me, however, that a strong irritation of the liver, while the cerebrum is exposed, will produce anæmia of the convolutions, but yet I do not mean to infer that such state of the liver in men or animals is productive of drowsiness, although that symptom is frequently met with in quite a number of liver complaints. I make that statement "en passant" because I know the stress that, with reason, is laid upon results of vivisection, and I think it but right to say that the state of the circulation *producing* sleep is a matter unknown as yet.

The intestinal irritation can cause hemiplegia under certain circumstances, a fact of the utmost importance in determining the real significance of the symptom palsy. Dr. Nicaire, of Paris, a distinguished surgeon, has lately brought before the notice of the surgical society of that city two cases which occurred to him. They were women past the critical period. The first suffered from right crural strangulated hernia. She had, as a consequence, left hemiplegia, with palsy of face of the same side; the attack came on gradually, and there was no aphasia; herniotomy was performed without opening the sac, and the patient was cured. The second was also right crural strangulated hernia. Hemiplegia supervened slowly, and was complete, limbs and face same side; as in the other case the mind was unaltered, and there was no aphasia; this patient died of peritonitis after the operation of kelotomy. Those cases, I repeat, have been reported by Dr. Nicaire especially to show that the palsy did not depend upon brain lesion by clot or otherwise.

I think that it is unnecessary to enlarge on the value and significance of the series of paralytic symptoms induced by a morbid influence exerted by diseased viscera upon the brain. I will now, gentlemen, try to offer an explanation for those phenomena, which, if acceptable, may probably suggest a mode of dealing with them efficaciously. I do not hesitate to say that those symptoms are all reflex in their nature, because there is no possibility of considering, for a minute, that irritation of the intestines, for example, will bring on paralysis in a direct manner. The reflex phenomena are brought about by the agency of vaso-motor nerves. At one time this system of nerves was the scapegoat in every disease; at the present time there is too little said about it. If a nervous system could be personified, this would be the one "qui ne meritait ni cet excès d'honneur ni cette indignité."

While discussing the pathology of reflex paralysis, which he thinks does not even exist, Prof. Vulpian states that, after all, lesions have always been found in such cases when the autopsies were carefully performed—I doubt not in the majority of cases. But nevertheless, the occurrence of the paralytic symptom contemporaneously with the visceral disease, I believe, go far to show a relation of cause to effect, and very certainly we all know that if a blood-vessel or a nerve-fibre be kept in an abnormal state for a length of time, their nutrition is impaired, and the parts which they subserve are *à fortiori* impaired. It matters not whether the impairment is brought about by dilatation or contraction, both permanent, of vessels. In the point at issue the fact to be kept in mind is that whether it be cases of the first series, *i.e.*, symptoms in the viscera during the occurrence of brain lesions; or of the second series, symptoms of brain affections during the existence of visceral diseases, we have to

deal with consequent, not a mere coincident element, and understand that it is always an irritative agent which is at work.

LISTER'S ANTISEPTIC METHOD IN OVARIOTOMY.

To the Editor of The Medical Record.

Sir:—In the last number of the Record, I took to myself the credit of being the first to use Lister's antiseptic method in ovariotomy.

By the *British Medical Journal* of the 25th of Nov., 1876, just received, I see that I was mistaken. At a meeting of the Pathological Society of London, held on Tuesday, the 21st November, "Dr. Griffiths, of Swansea, exhibited two desmoid ovarian tumors removed respectively from females aged twelve and twenty-one. They were both removed under the bichloride of methyline, the *carbolic spray* being also used."

"In both cases the pedicle was ligatured with the carbolized catgut, and then returned into the pelvis," and both cases recovered without any untoward accident. Yours, etc,

J. Marion Sims.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 3 to December 12, 1876.

Magruder, D. L., Surgeon. When relieved by Surgeon McKee, to proceed to St. Louis, Missouri, and report upon arrival there, by letter to the Surgeon-General. S. O. 250, A. G. O., Dec. 4, 1876.

McKee, J. C., Surgeon. To report in person to the Commanding Officer Department of Arizona, for duty as Medical Director of that Department. S. O. 250, C. S., A. G. O.

Lippincott, H., Asst. Surgeon. Ordered before the Army Medical Board, in session in New York city, for examination for promotion, and upon conclusion thereof, to rejoin his station, West Point, N. Y. S. O. 250, C. S., A. G. O.

Comegys, E. T., Asst. Surgeon. Assigned to temporary duty at Fort Clark, Texas. S. O. 216, Dept. of Texas, Nov. 28, 1876.

Prevention of Scurvy.—Mr. Robert Galloway, Professor of Chemistry in the Royal College of Science for Ireland, has recently published a pamphlet in reference to the prevention of this malady. His proposal is to restore to the salted meat the saline constituent which is removed from the flesh by the process of salting. This constituent is the phosphate of potash; and he suggests that it should be employed with salted meat, in the same manner as common salt is used with fresh meat. Mr. Galloway, who has a high reputation as a practical chemist, has brought the matter under the notice of the authorities, but, up to the present, has not been allowed a trial either in the navy or mercantile marine.—*British Medical Journal.*

Anæsthesia in Puerperal Convulsions.—Dr. John M. Julian, of Hoboken, N. J., thinks that too much reliance is placed upon anæsthesia in the general treatment of puerperal convulsions. Although the method is of unquestionable service in many cases, there is temptation to go to extremes which, in his experience, is not warranted. He writes:

"Whenever a two-thirds deposit of albumen is ascertained, scanty urine present, convulsions recurring either before or after delivery, and before a rapid pulse (the herald of danger), sets in, instead of placing our trust in the prolonged administration of anæsthetics —their benefit in such cases being limited to the alleviation of the eclamptic state—we should resort to the old—I feel sorry to say, rather neglected—practice of venesection, assisted, if need be, by the operation of transfusion. With the former we diminish, and with the latter we dilute as much as possible the poison contained in the blood. This is a ready method, and the only one, in my opinion, calculated to permanently quiet the recurring spasm, and re-establish the functions of the kidneys. In conclusion, I may be permitted to make the assertion, that in my own, as well as in the practice of others, I do not remember a single instance in which spontaneous diuresis became established that did not end in recovery."

Method of Preventing Cloudiness on Exploring Mirrors.—M. Sanundès, a medical student, communicates to *L'Union Médicale* (Sept. 23d) a new process of preventing the laryngeal mirror from becoming obscure. This consists of passing lightly over the mirror a cloth steeped in glycerine. The watery vapor contained in the expired air is dissolved completely in the glycerine and the cloud does not form. He proposes the extension of all glass and optical instruments liable to become obscured by cloudiness.

Scarlet Fever.—Mr. Pigeon, of Clifton (*Lancet*, November 25, 1876), claims marvellous success in the treatment of scarlet fever by the following method: "Anoint the patient twice daily with sulphur ointment; give five to ten grains of sulphur in a little jam three times a day." Besides this the room is filled twice daily with sulphur fumes. Under this treatment he says, "each case improved immediately, and none were over eight days in making a complete recovery, and I firmly believe that in each case it was prevented from spreading by the treatment adopted. One case was in a large school. . . . . As far as I can judge, sulphur is as near a specific for scarlet fever as possible."

Scurvy in the Arctic Expedition.—Despite the precautions taken by the British Government, scurvy attacked several members of the sledging parties. The cause of the outbreak is very innocently ascribed by the officers in command to the neglect in supplying the sledging parties with lime juice. The London journals very properly ask the question, Why this neglect?

Original Communications.

THE PROPER TREATMENT FOR LACERATION OF THE CERVIX UTERI.

By THOMAS ADDIS EMMET, M.D.

(Abstract of remarks made before the Medical Society of the County of New York. Phonographically reported.)

MR. PRESIDENT AND GENTLEMEN:—Two years ago I had the honor to deliver an address before this Society upon laceration of the cervix uteri as a frequent and unrecognized cause of disease, and I also pointed out a plan of treatment. Since that time expressions of disappointment have been given, because the results have not been gained which were promised. The failure to obtain such results as have been desired is due chiefly to want of proper care in the preparatory treatment for the operation.

If cellulitis has previously existed it will certainly return if every vestige of it is not removed before the operation is performed. Some have operated before the cysts, which form in the tissue of the cervix, have been properly emptied; before the congestion has been fully relieved; and before the parts have been gotten into the best possible conditions; and, as a matter of course, their operations have failed. Others have not properly denuded the surfaces to be united; have not observed due nicety in coaptating them after they have been freshened, and have failed to secure the desired results. For, it is necessary to obtain union by first intention. To this end the flaps should be freshened in such manner as to give as smooth and clean cut surface as possible, and then if they are adjusted with a reasonable degree of accuracy, and have been placed in proper condition preparatory to the operation, all congestion removed, etc., we may expect to obtain union by first intention. Cases are rarely seen in which the laceration does not need local treatment before operative interference.

Laceration of the cervix can be improved by treatment aside from operation; but the condition which has caused the woman to seek medical aid will invariably relapse, and it is for the purpose of preventing relapse that the operation is performed. It is to keep them well, after being under treatment. It has never been claimed that the simple operation will overcome every difficulty, but it will improve the local condition beyond what has been gained by previous treatment, and keep the patient from relapses. From one to three months are required for preparatory treatment.

The effect of the injury from child-birth is to arrest involution, if it be lateral laceration, in consequence of the irritation of the flaps, which separate as the woman assumes the upright position. If the accident occurs from very rapid labor or from the use of forceps with considerable traction, the perineum is ruptured not infrequently, and with this there is want of proper support to the uterus; it gets down upon the floor of the pelvis, and with the prolapsus there is also some degree of retroversion. Now when the woman attempts to walk, the flaps are forced far apart, the posterior lip catching in the cul-de-sac, and the anterior lip is crowded far forwards.

If after labor the cervix has cicatrized, glazed over, as the woman assumes the upright position, erosion forms again, there is profuse leucorrhœa, frequent show, backache, pains down the limbs, difficulty in walking, etc., and she seeks relief. When examined, the parts will be found to be congested, red, angry-looking, swollen, and in a condition which, until recently, has been mistaken for ulceration, sometimes for epithelioma, as well as for corroding ulcer of the uterus. As the lips of the wound are soft and become flattened, the injury cannot be readily recognized by the eye. Generally it can be recognized by the finger if the laceration is double, when the patient lies upon the back, because the neck of the uterus is felt wider than the body above. In cases in which there is any doubt, by drawing the posterior and anterior lips together the true condition will at once be revealed, and the neck is then often found to be smaller than natural.

Lateral laceration is often more difficult to detect, because the surfaces present an equal length upon both sides. When the laceration has taken place upon one side, the uterus becomes turned to the injured side, because of the inflammation which frequently follows the injury and attacks the nearest broad ligament.

This version results from shortening of the inflamed ligament, the two flaps gape, and with the uninjured side form a tripod with two legs shorter than the third one; the uterus, therefore, is necessarily tilted to one side.

In these cases the parts torn to the vaginal junction project into the passage at the same length of the uninjured side, and, being covered by the vaginal wall, the cervix presents a natural appearance. In cases of doubt, it is well to place the patient upon the knees and elbows, introduce a speculum, thus distending the vagina with air, and aiding gravity in bringing the uterus into its proper position, when it will be seen that a cleft exists in the neck of the uterus, extending perhaps not only to the vaginal junction, but into the vaginal wall itself.

When the uterus is tilted to one side from this injury, the sound can be passed in the median line to the fundus without giving by its use any indication of the true condition. The explanation is, that the sound passes through a patulous os and along the angle of the line upon one side of the cervix to the horn of the uterine canal of the opposite side; the direction from these two points being brought into the axis of the vagina from the position of the uterus.

The preparatory treatment consists in the systematic use of vaginal injections of hot water, counter-irritation in form of iodine or blisters over the region where cellulitis may have previously existed, emptying the cysts which have been formed by the gradual degeneration of the mucous follicles, keeping the flaps together by the use of cotton tampons saturated with glycerine in front and behind the cervix, and keeping the uterus anteverted as much as possible. The uterus should be lifted up by the finger, and should be retained in position by a properly-fitting pessary. When cellulitis has existed, it is very often found that it has been kept up by the entire weight of the uterus coming upon a shortened broad ligament. It becomes necessary in such cases to so fit a pessary that the dragging produced by the uterus will not be brought to bear upon such shortened broad ligament. But great care must be taken not to lift the uterus too high, for by so doing you will produce the same condition you wish specially to avoid. The cysts should be punctured with a small lance-shaped knife, stabbing the cervix in various directions. Scarcely an ounce of blood will be lost, as a rule; but if the hemorrhage be more than is desirable, it can be readily controlled by a vaginal injection of hot water.

After the puncture, Churchill's tincture of iodine is

brushed over the surface and carried into the canal, the flaps brought together and retained in position by glycerized cotton pads placed anteriorly and posteriorly. The puncturing must be repeated until the cysts have disappeared, and until the flaps have been reduced to the proper size.

The vaginal injection of hot water should be large, not less than a gallon, and should be repeated night and morning, administered with the woman lying upon her back.

As long as any tenderness can be detected in the neighboring connective tissue by pressure from the finger, the operation should be avoided, for you may be sure that a certain amount of cellulitis has previously existed, and that there is still remaining a condition which would require but slight provocation to re-establish the inflammation. After double laceration, partial constriction is often produced upon the neck as the parts cicatrize. This is often sufficient to obstruct the circulation in the flaps when aided by cystic degeneration. The starting-point is the irritation set up by forcing the flaps apart when the female is in the upright position; the mucous follicles become inflamed, their outlets get blocked up, and cystic degeneration follows, and as such cysts become distended by fluid, the mucous membrane will roll out to the os internum. From this cause the flaps become almost strangulated, and are placed in a condition similar to paraphimosis. In my former description of the operation, I advised that the surfaces should be freshened by means of scissors, leaving in the double laceration an undenuded tract of uniform width across the flaps, which, when brought together, would form the cervical portion of the uterine canal. Since that time, having closely watched the condition and changes after the operation in a number of cases, I have found that the os has frequently become too small. My rule had been to leave this undenuded tract at the width of the canal as it appeared at the bottom of the laceration, which is generally at the internal os. But when the canal was made of the same diameter between these hypertrophied flaps, it became too small after the operation, as soon as the uterus and cervix returned to the natural size. In my present plan I obviate this difficulty by leaving the freshened surfaces oval, so that the undenuded tract is now left trumpet-shaped. Now, as the uterus gradually returns to the normal size, this new canal becomes of a natural and uniform diameter throughout. To make the canal of the proper size, we must be guided by the amount of hypertrophy in the flaps. It must bear some relation to the increased size of the flaps, and the trumpet-shape is necessary, since the hypertrophy increases in degree from the bottom of the laceration towards the outer edges of the flaps. Immediately preparatory for the operation, I commonly have given a large vaginal injection of hot water, the effect of which is to contract the blood-vessels, and allow of only a moderate loss of blood. The mode of operating is to place the patient on the left side, and to use Sims's speculum or some other perineal retractor, to bring the parts into view. The first step is to bring the flaps together, and while they are lifted into apposition by means of a double tenaculum in the hands of an assistant, the uterine tourniquet is slipped over the cervix, below the point of vaginal junction, and tightened. Just before constricting the neck the precaution should be taken to draw up with a tenaculum, through the loop, sufficient vaginal tissue all around the cervix, that the flap may be brought together easily. The fold thus formed renders the tourniquet less liable to slip as the cervix becomes reduced in size from the escape of blood during the operation.

For freshening the surfaces I prefer the scissors, because of the greater rapidity with which the tissues can be removed. At the outer angles of the fissure the freshening should be as superficial as possible, for fear of cutting the circular artery. The introduction of the sutures is the most difficult step in the operation, on account of the mobility of the organ and the density of the diseased uterine tissue. I recommend that when the tissues are dense, the lance-pointed needles of Dr. Sims should be used, but when the parts are soft, the round needle should be employed. The short round needle has the advantage of making only a punctured wound, and the suture fills the track it has made so as to prevent the oozing of blood through the aperture, as sometimes occurs when the lance-pointed ones are used.

The round needle should, therefore, be used when possible. From three to four sutures are generally needed on each side. The first should be passed close along the bottom of the fissure, and should not involve the undenuded strip left to form the canal; the last, through the crown of the cervix, being more superficial, is easier of introduction, but needs to be passed with more care than the others, with the view of bringing the edges at the os and along the vaginal surface from this point into accurate apposition. If proper care is not taken, cicatricial tissue will be left, and it may be accepted as an axiom that a female is not well while cicatricial tissue exists upon the cervix uteri.

The sutures are secured in accordance with the plan recommended by Dr. Sims for the operation of vesico-vaginal fistula. The needle is armed with a short silk loop to which the wire is attached after it has been introduced. The ends of the wires are to be twisted over the "shield," but before being freed from the former should be bent over flat by means of a tenaculum, used as a fulcrum, under the suture at the end of the twist close to the line of union. The sutures are commonly removed at the end of ten days, and great care should be taken in withdrawing them, lest the edges of the wound be separated. The nearest portion of the loop should be cut, the woman lying upon her left side, so that it will continue to bind the parts in apposition until it has been drawn out. The suture nearest to the vaginal junction should be the first to be removed, for if tendency to gape in the line is seen, the remaining ones can be left several days longer, so that the ununited portion may heal by granulation.

The woman should remain in bed two weeks after the operation, and should not be allowed to get up for any purpose. The bladder must be emptied by means of the catheter. The bowels may be kept regular by proper diet, as there is no necessity of maintaining constipation as far as the success of the operation is concerned. On the second or third day after the operation, a vaginal injection of tepid water may be used if there is much discharge.

Lacerations of the cervix uteri are very common, and it is doubtful if a female can give birth to her first child without some degree of laceration taking place. But if slight, union may take place while the woman is in bed and the rent does not give rise to any subsequent trouble.

Lacerations through the anterior lip do no harm except to make vesico-vaginal fistulæ. They do no harm when backwards, except they run out upon the vagina and give rise to bands of cicatricial tissue which produce retroversion, or set up a peritonitis

from running into the cul-de-sac. It is only when the laceration is lateral that the chief trouble ensues. I have occasionally met with cases where it was impossible to demonstrate where the laceration took place, and yet the bad effects following the accident were recognized. It would seem as if partial laceration occurred from the internal os towards the outlet upon one or both sides without extending to the vaginal surface, while the mucous membrane prolapsed through the enlarged canal and os.

The appearance in such cases is that presented after dilatation with the sponge-tent when partial contraction has taken place above, and with dilated cervical canal the prolapsed mucous membrane can be seen through the patulous os. The cervix is generally but little enlarged in diameter, but the walls are thinner than natural. I have treated these cases by dividing the cervix through upon both sides, then increasing the width of the raw surfaces so as to narrow the canal, and bringing the edges together as for the lateral operation.

We frequently meet with cases in which nature has attempted to repair the injury, and there is left a dense mass of cicatricial tissue which has been formed by granulation in the angle. When this source of irritation exists there will be more disturbance of the nervous system than in the original condition, and the enlargement of the uterus remains. The only remedy for such cases is to remove by means of a V-shaped incision the entire mass, and secure the surfaces in apposition with sutures as in the operation for laceration.

When the case has been of long standing, numerous cysts are formed and ruptured, and as a consequence contraction takes place along the edge of the mucous membrane of the canal and vaginal cervix. The effect of this contraction is to evert the two former flat sides of the flaps into convex surfaces in relation to each other. Were we to simply freshen these surfaces in a superficial manner and attempt to bring them together, we should fail to approximate the outer edges properly without the sutures were twisted so tight as to cut out. This cicatricial tissue is so dense that, should union be secured, it will be only temporary. It is, therefore, necessary to remove entirely this projecting surface, and partially excavate, that the sides of the flaps may be brought into close contact.

After the operation for laceration of the cervix uteri the pessary is to be again introduced. For, if there has been retroversion, as soon as the woman begins to assume the upright position, of necessity the uterus begins to settle down upon the floor of the pelvis until by traction of the walls of the vagina upon the flaps an erosion is produced, and gives rise to congestion and increased size of the organ. The necessity for maintaining the uterus in its proper position is frequently entirely overlooked; not only as a measure of benefit before the operation, but as a real measure of obtaining beneficial results subsequent to its performance.

I have no hesitation in saying positively, and this conclusion has been reached as the result of a large experience, that not the slightest good will result from this operation without preparatory treatment.

The principles of the operation are simple, and its execution is not difficult under any circumstances; yet the greater success will attend the surgeon who looks most carefully to the details of the preparatory and subsequent treatment. Attention to the minutest detail is of the greatest importance; even more so in the this branch than in the field of general surgery, where its necessity has been so long and fully recognized.

A CASE OF PERITYPHLITIS, WITH OPERATION AND REMARKS.

By EDGAR HOLDEN, M.D.,

NEWARK, N. J.

Mr. K., residing in Hoboken, a stout, robust, and hitherto exceptionally healthy man, was seized with rigors and intense pain in the ileo-cæcal region on the 7th of November inst. The pain spread gradually over the whole abdomen, but chiefly expended itself on the hypogastric and hepatic region, the tenderness upon pressure being extreme.

The symptoms were such for several days as to lead to the conviction that an acute inflammation of the liver with peritoneal complication, and not a difficulty with the cæcum, existed. The temperature, however, was rarely above 101°, the pulse from 90 to 100; the skin moist, and the tongue, free from any particular redness, was covered with yellowish white coating. Excessive pain, anorexia, inability to talk or move without increase of suffering, the dorsal decubitus and gradual development of tympanitis led to a suspicion of deeper trouble, and on the seventh day the tenderness over the previously extensive area was evidently concentrated over the ileo-cæcal junction. An inguinal hernia of the right side, which had not been down since the beginning of the illness, complicated the case and also rendered the diagnosis somewhat uncertain. Waiting for rigors or some other evidence of suppuration, and finding none, the tympanitis being markedly increased, the pulse increased in frequency and cordy in character, with indications of high arterial tension, it was decided best to operate. It was now the twelfth day of the disease, and no satisfactory evidence of actual suppuration had prevented, save a very slightly increased and possibly only a fancied prominence over the supposed seat of trouble. An ordinary hypodermic syringe proved, however, the correctness of the conjecture that abscess existed, and upon withdrawing the needle a few drops of pus were found and examined under the microscope.

Through the kindness of the attending physician, Dr. Geisler, and a fortunate experience in a former paracentesis thoracis in a child of the family, every facility for operation was presented, and with the assistance of several prominent physicians the following operation was performed Nov. 18, 1876. After the induction of anæsthesia a more careful exploration of the abdomen gave rise still to doubt as to the presence of pus, and the hypodermic needle was again introduced as nearly as possible in the direction of the former puncture. About twenty drops of unmistakable pus of exceedingly fetid character were obtained. The dulness extended from the ileo-cæcal region upward to the liver, and over an area about four inches in width, but not downwards, as would naturally be expected.

A curvilinear incision was now made two and one-half inches in length, its centre just below the point of puncture of the needle and one finger's breadth distant, and in front of the anterior superior spinous process. A thick layer of adipose tissue rendered considerable tension on the retractors necessary, and when after careful dissection the fascia transversalis was being punctured, a sudden gush of disagreeable pus escaped, amounting to a little more than a pint, at first yellow, then sanguineous, and very dark in color. My finger was introduced, and the appendix vermiformis, surrounded with thickened tissue, could be felt at the lower extremity of the cavity, the ascending colon pressing towards the outlet, but evidently separated

from it by a thin wall, probably the peritoneum. No opening could be detected into the bowel or appendix. After an injection of warm salt water, a tent of lint was introduced, and the upper part of the incision closed with a deeply inserted wire suture and a large poultice applied. On the day following (Nov. 19th), the tympanitis had disappeared, pain considerably less, and the pulse again at a normal rate. From two to four grains of opium were given in the following twenty-four hours, according to the judgment of the attending physician, and yet a free evacuation of the bowels was had with little or no pain. A glass drainage tube $\frac{5}{8}$ of an inch external and $\frac{1}{4}$ internal diameter, with a bulb at one extremity and just long enough to enter the opening in the transversalis fascia, was introduced and secured by cord and adhesive straps, the poulticing being continued. Nov. 21st.—All symptoms favorable, no rise of pulse or temperature, and but little discharge; salt warm water again injected, both for cleansing and the ascertaining of amount of contraction of the abscess walls. A nodulated mass could now be felt through the abdominal walls at the site of the appendix. Opium in grain-doses twice daily. Milk punches and beef tea *pro re natâ*.

Nov. 23d.—Very greatly improved, free from pain, and able to move in bed without difficulty. The discharge upon the poultice small and of better character. The drainage tube was now removed, and the wound and cavity cleansed with the warm salt water as before. The suture in the upper part of the incision was also removed, healing having occurred. So far as could be ascertained by the fluid injected, the abscess cavity was nearly obliterated, a hard mass being distinctly felt over the ileo-cæcal region. Abdomen very slightly tympanitic again, but pulse, respiration and temperature normal.

Nov. 27th.—Patient free from all abnormal symptoms and apparently well, with the single exception of the still open wound in the abdomen. The discharge partly of laudable pus, partly of blood. The locality of the abscess clearly traceable upon careful percussion, the ileo-cæcal mass softer and smaller. Poulticing to be continued for a few days.

Dec. 1st.—Thirteen days after operation. The patient appears well, but very weak, is free from all pain and tenderness, rises in bed without difficulty, and but for a slight cold, contracted by exposure to a draught of air from a window, would be able to be out of bed; is only conscious of weakness when trying to walk. The abdomen wound has entirely healed. No foreign substance has been found in the discharges.

That this patient would have died if a few hours of longer delay had been allowed, can scarcely be doubted. The abscess wall was exceedingly thin, the intestines pressing forward into the incision, and the sensation being to the finger as if inside the peritoneal cavity, while the thickened fascia and muscular abdominal wall showed no evidence of yielding before the accumulation.

The infinitesimal prospect of a discharge into the intestine itself can hardly be considered.

Everything favored operation, and the entire absence of adverse symptoms after the operation was all that the most sanguine advocate of such procedure could desire. The failure to obtain any foreign substance in the discharge might seem to militate against the idea of an origin in the appendix; but (aside from such failure being no proof that a substance was not discharged) the perceptible hardness over the appendix for several days subsequent to the operation, and similar failure in several of the cases recorded by Dr. Buck in a pamphlet on the subject two years since, show that such origin (in the appendix) was probable.

That the abscess resulted from inflammation, *περι τυφλον*, and was therefore truly perityphlitic, and that prompt operation was proven justifiable by recovery, are the chief points of interest.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

EPILEPSY—CESSATION OF THE FITS AFTER A SEA VOYAGE—RETURN OF THE DISEASE.

The case illustrated a fact occasionally noticed, namely, a cessation of the convulsions of epilepsy immediately upon making a trip across the ocean. The patient was seventeen years of age; had had the fits since he was three months old, until five years ago, when he came to this country from Ireland. After his arrival the fits almost entirely ceased, but had returned, and it was for their treatment that he had come to the hospital. In certain cases of epilepsy a marked improvement in regard to the occurrence of convulsions is brought about by a trip at sea. Another practical point was illustrated by the case. It was very difficult to determine to what extent his intellect had been affected, for the reason that the boy had never been sent to school, or rather he was not allowed to remain in school, and his education had been entirely neglected at home. It was regarded as a point of special importance that epileptics should be regularly subjected to mental exercise.

PROLAPSUS UTERI CAUSED BY TRACTION FROM BELOW—SUPER-INVOLUTION OF THE UTERUS—RECTOCELE—CYSTOCELE—RARE COMBINATION.

The patient was a woman, æt. 37 years, who had been married sixteen years, was the mother of twelve children, the youngest sixteen months old, and she had also had two miscarriages. Her chief symptom was a burning heat in the vagina. She had had no menstrual discharge for six months. Upon examination it was found that a most remarkable atrophy of the uterus had taken place, the cervix almost entirely gone, the body not more than one-half its normal size; and that but little involution had occurred in the vagina and perinæum. The cessation of the menses could therefore be readily explained. The sub-involution of the vagina and perinæum had given rise to the rectocele and cystocele. This little uterus had already settled from its normal position, and it was prophesied that ultimately the organ would be dragged down and out from the woman's body by the traction made by the prolapsed vaginal walls. It was thought the condition of the patient, with reference to the cystocele and rectocele, might be improved by operative procedure, although the prospect of success was not at all flattering.

PROLAPSUS UTERI CAUSED BY DIRECT PRESSURE FROM ABOVE—POLYPOID GROWTH IN THE URETHRA.

The patient, æt. 60 years, had suffered from vesical tenesmus two months, and it had been so severe that prolapse of the uterus had been produced. The irresistible and continuous desire to evacuate the bladder had kept up a constant bearing down; expulsive effort and displacement of the uterus had been the result.

But what gave rise to the vesical tenesmus? Upon examination, a small polypoid growth was found in the urethra. It would be hardly fair to say that a urethral polypus had caused prolapsus uteri, but it had acted as a cause in exciting an influence that did give rise to such a condition.

HYDRORRHŒA—CARCINOMA OF THE CERVIX.

The chief interest in this case was the sparseness and yet the gravity of subjective symptoms. Menstruation had ceased six months ago; three months ago the woman began to have a watery vaginal discharge, which had continued up to the time of the examination, and which had recently been tinged with blood. There was a fixed pain above the pubis, and so severe that the woman was unable to sit still. Her face was haggard.

On physical examination, an exceedingly friable fungous growth, which bled upon touching it, was found involving the entire cervix uteri, and probably passing beyond the vaginal junction into the body. All that was recommended in way of treatment was to let the woman take opium sufficient to make her comfortable, and to use an injection composed of tannic acid ʒ i., carbolic acid gr. xv., and water Oj.

If the growth had involved only the cervix, and to only such an extent as would permit of amputation by means of the galvano-cautery wire *above* the disease, the operation would have been recommended.

PREPUTIAL CONDYLOMATA, BENIGN IN CHARACTER.

A few suspicious-looking growths were seen upon the prepuce of a young man, whose statements were such as to entitle him to full credence, and it was believed that they had occurred independent of gonorrhœa, chancroid, or chancre. In other words, they were believed to be of non-specific origin. They were snipped off with scissors, and the stump was cauterized with chromic acid.

URETHRAL STRICTURE INDEPENDENT OF ANY ANTECEDENT GONORRHŒA OR POSITIVE INJURY WHICH CAN BE ASCERTAINED.

The young man had been sent for treatment on account of some nervous trouble, his physicians suspecting that the pains in the back, gradually extending over towards the groin, and finally down the groin and upon the inside of the thigh, and accompanied by dribbling of urine after the act of urination was supposed to be completed, was due to some urethral irritation. A careful investigation had also excluded masturbation from the history of the case. Upon examination, it was found that the meatus urinarius was abnormally narrowed, and it was remarked that perhaps in 99 out of 100 cases of trouble after micturition this condition would be found to be present. The meatus was cut until it admitted a 32 French scale.

SYNCOPE ATTENDING THE INTRODUCTION OF A URETHRAL SOUND.

The case was interesting as showing the intimate relation existing between the nervous system and the genito-urinary apparatus. The first time the instrument was introduced into the patient's urethra, he toppled over in a fainting fit. It was said that this seldom occurred but once, and that, as a matter of precaution, it was well always to have the patient placed in the horizontal position whenever, for the first time, the urethra is to be explored.

FRACTURE INVOLVING THE ELBOW-JOINT.

The principle involved in the treatment of the two cases seen, although not new perhaps, is of sufficient interest to warrant repetition. The danger to be avoided is anchylosis. The method of treatment was believed to be applicable to all cases involving the joint.

1. Extension until primary irritation has entirely subsided.

This can be done by means of the weight and pulley, with the arm in a straight position.

2. When the irritation has subsided, then lock the limb up in a plaster-of-Paris splint, with the fore-arm flexed at a right angle with the arm and placed midway between pronation and supination.

3. After it has remained locked up for perhaps ten days, the splint should be removed and gentle passive motion commenced and persistently kept up until motion at the joint is secured.

Two prominent obstacles to carrying out this plan, are the groans of the patient and the timidity of the young surgeon. One is quite apt to be excited by the other, but the latter must be set aside to a very great extent if the groans of the patient are not subsequently to be turned into curses when he finds out that he cannot even wipe his own nose with the hand belonging to the injured member. In the cases before us this manipulation could be performed with great ease and comfort, and the hand could also be carried to the top of the head without difficulty. The results thus far were exceedingly favorable, but by persistent continuation of the passive motion it was believed that the movements of the limb could yet be materially improved.

In another ward, and under the charge of another eminent visiting surgeon, a case of like character with the above was seen, and the plan of treatment strongly insisted upon was, that the joint should be let entirely alone until all inflammatory action had disappeared (we are now speaking with reference to overcoming the tendency to anchylosis invariably present), perhaps six weeks, or even more, and then little by little the rigidity could be overcome, daily moving it, making flexion and extension more and more, until at the expiration of four, five, or six months good motion could be established; the patient reaching his own nose, mouth, throat and head, etc. It was said that the patient could be anæsthetized and full flexion and extension made; but that procedure was objected to upon the ground that the joint would certainly relapse into the former semi-anchylosed condition, perhaps be made worse, and that ultimately the slow process of overcoming the rigidity would be necessitated.

The timidity of the young surgeon in this instance might be regarded as a valuable accomplishment.

AORTIC INSUFFICIENCY—LITTLE OR NO COMPENSATORY HYPERTROPHY.

One or two practical points presented themselves in the case before us which are worthy of mention.

1. The fact that little or no cardiac hypertrophy attended the aortic lesion rendered the prognosis unfavorable, because what the heart needed was more powerful walls to counteract the effect produced by the valvular insufficiency and restore equilibrium to the circulation. As it was, the man suffered: 1, from cardiac disease; 2, from interference with the venous flow; and 3, imperfect digestion, as the result of chronic congestion produced by such interference with the circulation. He therefore had lost flesh and strength, and was in an anæmic condition.

What was to be done for the patient under such circumstances?

It was remarked that the rational treatment would

be to make the heart act, and so restore the cardiac impulse that it would remove the venous congestion; but as a matter of practice it was believed to be better to begin at the other end, and treat the results produced by the obstructed circulation. The man was anæmic, hence iron was indicated. His digestion was bad, and although dependent on the cardiac disease, an effort was made to improve it by the use of such a remedy as would favor a restoration of the appetite and assist the digestion. Subsequently, treatment could be directed to the condition of the heart itself. The first remedy prescribed was citrate of iron and quinine in ten-grain doses three times a day, before meals. In addition, for that particular case, it was recommended to give the following:—

℞. Pepsin..... grs. x.
Acidulated wine (Rhein or sherry)... ℥ ii.
Acid. hydrochlor. dil..... gtts. xx.
M.

To be taken with each meal.

ANEURISM OF THE ARCH OF THE AORTA—ADVANCED CONDITION WITHOUT SPECIAL SYMPTOMS—STRIDULOUS COUGH.

A male patient, æt. forty-four years, a laborer, without history of constitutional syphilis, noticed "something in his swallow" about eight months since, and nine weeks ago had an attack of bronchitis, which for several days had been preceded by a smothering cough.

Near the junction of the second intercostal cartilage with the sternum was a rounded tumor, elevated about half an inch above the surrounding parts, pulsating synchronous with the heart-beat, and when auscultated gave a *bruit*. This tumor seemed to have been developed imperceptibly, and had not been attended with the usual pain, although the pressure had been sufficient to cause it to make its way through the chest-walls and show itself externally. There was a stridulous cough, but the fact that the respiratory murmur was exceedingly feeble was regarded as evidence that it was probably due to pressure upon the trachea.

VARICOCELE—SIX CASES TREATED BY ONE METHOD.

We saw seven cases of varicocele, in five of which the disease was confined to the left side, and in the remaining two it was developed upon both sides. Six of those patients were under treatment by means of mechanical pressure afforded by a truss, and this was aided by a suspensory bandage. The odd case, the disease being only slightly developed, was treated by means of the suspensory bandage alone. Support the pendant parts and at the same time make moderate compression immediately over the external abdominal ring. To make pressure, an ordinary hernia truss was used, with the addition of a perineal band to secure it perfectly in position. The aim was to make such an amount of pressure as would moderately compress the veins at that point, and maintain it night and day, the truss being removed only for purposes of cleanliness. It was believed by the visiting surgeon that we should not resort to any more violent means of cure in a majority of cases, and that in a large proportion favorable results might be expected.

DIABETES MELLITUS—EXHIBIT OF THE QUANTITY OF WATER DRANK AND THE QUANTITY ELIMINATED BY THE KIDNEYS.

The case was interesting because it illustrated the statement that the diabetic patient eliminates more water, by way of the kidneys, than he drinks.

There has been a strong conviction that the consumption and elimination of water may be equal. The specific gravity of the urine in the case before us was 1036, and it contained sugar as demonstrated by Trommer's & Fehling's tests.

Oct. 5, the man drank 15 pints of water and passed 150 ounces.

Oct.	6,	drank	13	pints	and passed	120	ounces.
"	7,	"	14	"	"	130	"
"	8,	"	12	"	"	110	"
"	9,	"	11	"	"	106	"
"	10,	"	14	"	"	150	"
"	11,	"	13	"	"	146	"

His treatment consisted in the administration of one grain of opium three times a day. Milk, eggs, and meat were the chief articles of diet.

Progress of Medical Science.

DEATHS FROM VIPER-BITES IN FRANCE.—M. Vian-Grand-Marais has collected the notes of three hundred and seventy cases of viper-bites which have occurred during the last twenty years in the departments of the Loire-Inférieure and of La Vendée. Fifty-three of these cases proved fatal. Many distinguished scientists and physicians maintain that the bite of the viper is not fatal to man, but these figures show the danger of allowing such a theory to be propagated.—*Journal de Méd. et de Chir.*, November, 1876.

ŒSOPHAGOTOMY.—M. Cazin, of Boulogne, has recently performed this operation under the following circumstances: a woman swallowed a piece of bone, which became impacted in the œsophagus in such a way that it could not be pushed down into the stomach. M. Cazin decided to perform œsophagotomy, although a considerable degree of hypertrophy of the thyroid gland rendered the operation difficult. When the foreign body was reached, the surgeon seized it with forceps, but could not remove it without risking a dangerous laceration of the mucous membrane. He then had recourse to a procedure employed by Velpeau, which consists in introducing into the œsophagus a piece of pasteboard rolled up in such a way as to surround the foreign body and thus detach it from the mucous membrane: by this method the bone was removed without difficulty. In closing the wound, M. Cazin employed separate sutures for the two tunics of the œsophagus, so that the internal sutures ran no risk from the contractions of the muscular tunic. An œsophageal tube was introduced through the nares and left in position for twenty-eight hours. The patient was fed through the tube, and in this way the difficulty of nourishing her was removed.—*Journal de Méd. et de Chir.*, November, 1876.

NERVOUS COUGH DUE TO ANTEVERSION OF THE UTERUS.—Malachia de Christoforis reports the case of a woman, aged twenty-three years, who had been treated for a nervous cough for a long time with antispasmodics, but without success, and was finally sent to him for a laryngoscopic examination. The patient had been pregnant once, two years before, but she aborted at the third month. Since then she had had a slight leucorrhœa, and lumbar pains, which were augmented by walking or standing. The examination of the thorax, abdomen, and larynx gave negative results. There were no painful points on the vertebral column. The cough occurred only during the day, and consisted of frequent, short paroxysms, with intervals of repose varying from half an hour to two hours. No expectoration. The cough ceased

immediately when the patient lay down. For over a year she had often suffered from dysuria.

A vaginal examination revealed marked anteversion and considerable enlargement of the uterus. In the dorsal decubitus the organ resumed very nearly its normal position. The uterus was replaced and kept in position by Hodge's pessary, and the cough stopped at once. A few days later the pessary was withdrawn, but the anteversion was then reproduced, and the paroxysms of coughing returned and continued until the pessary was reapplied. At the end of a year the uterus was very much diminished in size, and the anteversion so much modified that the patient did not cough even when the pessary was removed.—*Le Lyon Médical*, November, 1876.

New Test for Albumen in the Urine.—At a recent meeting of the *Société de Biologie de Paris* M. Bouchard read a paper on the employment of the double iodide of mercury and potassium as a test for albumen in the urine. According to him, the test is very delicate, and so much so that the absence of albumen may be positively affirmed, when the urine does not cloud on the addition of this reagent. There are certain sources of error in the test, however, which must be borne in mind:

1. The error may depend upon the reagent itself, when it can be easily avoided by adding an excess of iodide of potassium to the solution.

2. If mucine be present in the urine, or white precipitate analogous to the albuminous precipitate, it is formed on adding the double iodide, but it forms slowly, while albumen is thrown down at once.

3. If the urates be present, a precipitate may also be thrown down, but it forms slowly in the middle, instead of at the bottom of the test-tube; is not flocculent; and finally disappears under the influence of heat.

4. When the urine is alkaline, a precipitate may form even if no albumen be present, but it has a gray color, and becomes black in a few seconds.

5. The presence of alkaloids in the urine may also lead to the formation of a precipitate, but it is not flocculent, begins to form in the middle of the test-tube, and disappears under the influence of alcohol or heat.

In a word, every precipitate which persists after the employment of heat is due to the presence of albumen in the urine.—*Le Lyon Médical*, November, 1876.

Mode of generating Sulphurous Acid.—Mr. Thomas W. Keates suggests a ready and simple method of producing this acid for disinfecting purposes. Bisulphide of carbon, when mixed with petroleum and burned in a properly constructed lamp, will generate sulphurous acid with the other usual products of combustion. In a room containing thirteen hundred cubic feet of air, it was found that by burning two hundred and eighty grains of the bisulphide with a single wick, the atmosphere became so charged with the sulphurous acid, that it was impossible to remain in the room more than a few seconds. In twenty minutes after lighting the lamp, the air was unbearable. Mr. Keates has designed an apparatus for the purpose of disinfecting, which consists of a lamp enclosed in a metal case about three inches in diameter, and eight or nine inches high, with holes at the bottom for the admission of air, and others in the top for the escape of the sulphurous acid. This can be carried about and left in closets, holds of ships, etc., and, it is said, without any danger.—*The Lancet*, November 18, 1876.

Trepanning as a Prophylactic.—M. Sédillot has already presented several communications to the *Académie des Sciences de Paris*, recommending preventive trepanning in cases of fracture of the skull with splintering of the internal table, to avoid the usually fatal complications of this injury. He has now collated one hundred and six cases of this sort of injury, which he publishes in support of his recommendation. Of these cases seventy-seven were trephined and twenty-nine were not. Nine of the operations were preventive—that is, they were performed before the appearance of the primitive or consecutive accidents; sixty-eight were curative—that is, they were performed to remove grave complications such as paralysis, convulsions, or coma. In twenty-one of the one hundred and six cases the external table was not fractured; and as the symptoms, in most of these cases, were not marked, the injuries were often thought to be slight.

Of the twenty-nine cases that were not operated on, one recovered and twenty-eight died; of the nine cases in which preventive trephining was performed, six were cured; of the curative trephinings, twenty-one were performed during the first five days after the injury, and eight of the patients recovered; forty-seven were performed after the fifth day, and fifteen patients recovered. The mortality was consequently proportionate to the delay in the application of the trephine. When the operation was preventive two-thirds of the patients were saved; when it was curative, but performed early, over one-third were saved; when performed late, less than one-third; while only one case in twenty-nine recovered without an operation.

In the diagnosis M. Sédillot suggests that auscultatory percussion may help the surgeon.—*Le Lyon Médical*, November, 1876.

Aneurism of the Arch of the Aorta that simulated a Pleuritis Sinistra.—Marc F——, a drayman, thirty-eight years of age, of a robust constitution, was suddenly seized with a violent stitch in the side and intense dyspnœa, while walking alongside his cart on July 31st. He fell in the street and had to be carried to his home. Fifteen days later he was removed to the hospital De la Croix-Rousse, in Lyons, where he was placed under the care of M. Soulier. At that time the stitch had disappeared, but the oppression persisted; respiratory movements, 40; pulse, 104; slight cough. A physical examination revealed flatness, loss of vocal fremitus, and loss of the vesicular respiratory murmur over the whole of the left lung. A slight, soft murmur was heard posteriorly over the situation of the left bronchus. The voice-sounds were the same over both lungs, but the whisper-resonance was exaggerated on the left side. Mensuration showed that the left side of the thorax was not enlarged. A diagnosis of pleurisy was made. On September 2d the patient had a severe attack of hæmoptysis. On September 9th he had another attack of hæmoptysis, in which large clots of blood were coughed up, and which proved fatal in a few minutes.

At the autopsy a small sacculated aneurism, as large as a nut, was found on the under surface of the arch of the aorta. The aneurism was filled with a firm clot, and it compressed and obliterated the left bronchus. The clot and the thin aneurysmal sac presented fissures which opened into the left bronchus, and through which the terrific hemorrhage took place. There was complete splenization of the left lung. The right lung and both pleuræ were perfectly normal. The case is of interest on account of the difficulty of the diagnosis.—*Le Lyon Médical*, November, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 23, 1876.

THE METRIC SYSTEM IN PRESCRIPTIONS.

Before discussing the comparative merits of the metric and our present system, it will be desirable, we think, to succinctly state the principles upon which the former depends, so far as it relates to pharmacy and the dispensing of medicines.

In this connection we deal with a single unit, the Gramme,* equal to a little less than 15½ grains Troy. All integral quantities are expressed in multiples of this, and all fractions in decimals, the decimal point being always placed in its proper position between the integers and the fraction, in the same way that we place the *point* between dollars and cents in monetary notation. The fractions have definite names according to the position which their units occupy, thus *grammes* 1.642 may be read, one gramme, six decigrammes, four centigrammes, and two milligrammes, just as in our currency the figures $1.642 may be read one dollar, six dimes, four cents, and two mills. This form of expression, however, is seldom employed, as we usually confine ourselves to *dollars* and *cents*, at the same time always having in mind the meaning and relations of the dime and mill. In metric pharmacy, likewise, the gramme and centigramme are the terms usually employed.† For instance, it is customary to say thirty centigrammes in preference to three decigrammes, just as we say thirty cents, rather than three dimes, although either form is correct. The *milligramme* in pharmacy, like the *mill* in currency, is rarely used, simply because so small a quantity is seldom called for. The terms decagramme, hectogr., and kilogr. are not used in prescriptions, the number of grammes required, being expressed in ordinary Arabic numerals.

The extreme simplicity, therefore, of metric pharmacy, and its absolute correspondence in principle and detail with our own currency system, are features not to be overlooked. The above is the whole of the metric system so far as it immediately concerns us.* The manner in which one can at present use it may be best shown by an example.

Premising that

		Grammes.
gr. i.	=	0.064
gr. xv.434.	=	1.000
f ℥ i. (U.S.)	=	29.544
℥ i. Troy	=	31.103

we immediately perceive that if we desire to transpose an ordinary prescription into a metric one, we can in the great majority of instances dispense with fractions (in our mental calculations), and use convenient approximations, thus:

		Grammes.
gr. i.	=	0.06
gr. xv.	=	1.00
℥ i.	=	30.00

The following prescription, therefore, metrically expressed, becomes:

	Grammes.
℞. Hydrarg. bichlor. (gr. ij.)	0.12
Potassii iodidi (℥ ss.)	15.00
Syr. sarzæ co. (℥ iv.)	120.00

M.

Dose, teaspoonful three times a day.

In reference to the above we ask attention to several points. First, it is expedient for the present to write the word *grammes* in full, over the first line of figures.† Second, whenever a less quantity than a gramme is ordered, the zero (0) should always be placed before the decimal point. It will be noticed in the example given, that the *syrup* is ordered by *weight*. This is in accordance with Continental usage, the German Pharmacopœia expressly stating that every ingredient in an officinal preparation shall be determined by weight.‡ The use of the cubic centimetre, as suggested by some,§ would throw us out of uniformity with European practice, and would be attended with many of the evils which accompany our present employment of measures of capacity. If we are going to use the metric system at all, let us employ it properly, and in conformity with established usage. When a *small* quantity of a fluid is prescribed, it is often the custom to order it in *drops*. This may also be done in metric prescriptions. Many physicians, however, aware of the varying size of drops in different preparations, prescribe small quantities in *minims*, and are innocent enough to believe that the apothecary dispenses accordingly. We venture to say that not one druggist in ten measures the

* The complete system of metric weights is as follows:

1000	100	10	1	.1
kilogramme,	*hectogramme*,	*decagramme*,	GRAMME,	*decigramme*,

.01	.001
centigramme,	*milligramme*.

† "Les auteurs de formulaires recommandent tous de ne se servir que des termes *grammes* et *centigrammes*." Dorvault, *L'Officine*, Paris, 1875, p. [illegible].

* We shall not here discuss metrics in its relations to measures of length, area, or capacity, as these are not involved in pharmaceutical operations.

† Some physicians in this city have the word printed upon their prescription blanks at the upper right-hand corner.

‡ *Mensuris nunquam, sed semper ponderibus liquorum quantitas indicanda et determinanda est.* Pharm. Germ. 1872, p. XII.

§ The Medical Register of New England, 1876.

minims with a *pipette*, the proper way, or even with a minim graduate, but simply gives as many drops as are ordered minims in the prescription. The minim and the drop, then, being to the apothecary practically the same, the abandonment of the minim will not be much of a loss to pharmacy. Domestic dosage is the same in the metric as in the old system, the teaspoon, tablespoon, etc., being used as heretofore.

Having now explained the principles and practice of metric pharmacy, we are in a position to consider its advantages and disadvantages, as compared with our present system.

RELATIVE ADVANTAGES.

℞ Metric System—Simplicity.	Old System—Complexity.
I. A single unit—the *gramme*.	Five units of weight—*grain, scruple, drachm, ounce, pound.* Four units of capacity—*minim, fluidrachm, fluid ounce, pint.*
II. All medicinal substances are dispensed by weight.	Some are dispensed by weight, others sometimes by weight, and sometimes by measure.

III. Convenience in calculating and altering formulæ (metric). If, for instance, in the prescription above given, it seems desirable, upon a patient's second visit, to increase or diminish the quantity of the active ingredients, this is readily effected by the addition or subtraction of a few centigrammes, the quantity of menstruum and dose remaining the same. If, again, the formula is suitable for an adult, and we wish to graduate it for a child, and make it only one-sixth as strong, the prescription would be:

	Grammes.
℞. Hydrarg. bichlor.....	0.02
Potass. iod.....	2.50
Syr. sarzæ co.....	120.00

M.

S.—Teaspoonful three times a day.

If, now, we wished to effect this same apportionment in the original prescription, written in the usual manner, we would be obliged to write, *Hyd. bichlor.* gr. ⅛, a quantity which the apothecary could not directly weigh (for lack of a ¼ gr. weight). He would therefore weigh out one grain, and divide it by guess-work into three portions, one of which (perhaps equal to the others, but probably not) would be dispensed. Coming now to the iodide of potassium, the ℥ss. would have to be reduced (in the prescriber's mind) to grains, 240, and this divided by 6, giving 40, and this changed to Roman notation, xl.; and, five times out of six, we would have to give a special extra thought as to whether the x comes before or goes after the l.

In comparing, then, the relative merits of the two systems, we find that the advantages appear to be all upon one side; and we frankly confess that, if there are any comparative disadvantages in the metric system, we have thus far been unable to discover them.

The question as to the *expediency* of the adoption of the metric system in prescribing will be considered in our next.

THE MANAGEMENT OF OUR ASYLUMS.

FROM a popular point of view the office of medical superintendent of a lunatic asylum is not a very desirable one. Judging from the reports in the daily papers of maltreatment of patients, it would appear that as a class, the physicians are not only neglectful of their duties, but positively cruel in their ministrations. It is so easy to create a sensation by detailing the wrongs of some poor lunatic, that it is not a matter of surprise that the reporters of the daily press seize upon the slightest pretext for so doing. The apparent plausibility of these stories is such as to create a profound impression upon a sympathizing public, and react in a manner that is in the highest degree detrimental to the best interests of the asylums.

The medical profession, however, are prepared to take the stories for what they are worth, and place their own interpretation upon the animus which dictated their circulation. From the character of the medical superintendents of these institutions we have a right to believe that the charges of intentional inhuman treatment are entirely groundless, and we should be content to suspend judgment until the time for vindication arrives.

A week or two ago the daily papers detailed the account of a helpless female, who for no apparent reason was hastened to a lunatic asylum, and there kept in forced confinement for several days. To other sensitive and lone females, who were liable to become disabled in the street, this was not a very assuring evidence of personal safety in a free country, and no doubt many read the dramatic descriptions with feelings akin to positive horror. It is needless to say that the matter was duly investigated by the authorities, when it was proved that the poor woman was really insane, and a fit subject for treatment in an asylum. Then the papers became silent on the question of right and justice in the matter; and so it was, from a sensational point of view, judiciously, if not ignominiously, dropped.

Next in the course of events, and as a needful seasoning for dull and unsatisfactory political news, another victim of asylum cruelty is found, who is duly interviewed by a reporter, and another horrible story started. It is stated that a helpless patient was driven naked to a bath through a long hall, was confined in a strait-jacket, and otherwise roughly used at the option of her attendant; and that she was so forcibly fed, that the instrument used for the purpose inflicted a serious injury upon her palate.

On its face this also appears to be a very bad case. If, however, we consider the ordinary difficulties in the way of treatment of the class to which the patient belonged, it is easy to place a charitable construction on the worst possible interpretation of the affair. At least, so far as the investigation has gone, there is no proof that the medical superintendent was remiss in his duty, or that the attendant wilfully abused her trust.

THE ARCTIC EXPEDITION.

The English journals are still discussing the causes of the recent failure of the Arctic expedition. The general opinion seems to be that the greatest difficulty in the way of success was the occurrence of scurvy. It now appears that the latter disease was due to a neglect to supply the men with sufficient lime-juice, and that such neglect was owing to the fact that the commander of the expedition did not believe in its efficacy. It would seem from this that our own naval authorities have not erred in their recent interpretations of naval discipline. From present appearances, however, our cousins are not to be held altogether blameless for their presumptive interference with the duties of the medical staff.

PROBING OF WOUNDS OF CAVITIES.

We are gratified to learn that in a recent case of gunshot wound of the abdomen, admitted to Bellevue Hospital, that no attempt was made to search for the ball by probing. This is such an exception to the general rule in cases admitted to hospital, that it deserves special mention. In the present instance the patient will evidently have the best chance for recovery; and, in case of death, which from present indications is not improbable, there will be no question concerning any meddlesome interference on the part of the surgeon in attendance.

Gunshot Injury of the Musculo-spiral Nerve.—Dr. E. Owen was consulted by a gentleman, October last, who was injured a year previous by the accidental discharge of a gun loaded with corn-shot. The contents entered the arm, and at the time of the examination by Dr. Owen (Oct. 11) there was numbness over the back of the head, with no power over the extensors of the thumb or fingers. The pronator radii teres and the flexors of the wrist and fingers retained their power. For some time after the accident there was no sensation over the back and outer side of the forearm, but at present he feels a pinch, like the sensation caused by a red-hot iron. He is recovering the use of the hand, under the care of Dr. Kellgreen, of the Swedish Institute. The treatment consists of various gymnastic and manipulatory exercises. The shot-corn (twenty-four in number), searched for in vain by the surgeons, have worked up from the deep tissues to the skin during this treatment.—*The Lancet*, November 18, 1876.

Reviews and Notices of Books.

Transactions of the New York Pathological Society. Vol. I. John C. Peters, M.D. Editor. New York: W. Wood & Co., 1876. 8vo, pp. 272.

Although the New York Pathological Society has been in active existence since 1844, and has during the past twenty years ranked as the foremost medical organization of the country, it has not, until the present year, fulfilled the oft-expressed determination of publishing its transactions in book-form. In view of the immense amount of material which has been accumulated by the faithful and accurate reports of the various secretaries, it was, after much deliberation, decided to base the present volume upon the proceedings of 1875, and supplement the reports of the various cases with similar ones which had been recorded since 1844. Dr. Francis Delafield was the first editor appointed. This gentleman for several years labored successfully in arranging the vast quantity of manuscript material, and on his resignation Dr. John C. Peters was appointed to the office, when these labors were continued with a zeal and purpose which have so happily culminated in the present volume.

The arrangement is purely an anatomical one, and will be acknowledged to be the best that could be made. After giving a very interesting account of the origin and rise of the Society, a list of the specimens of 1875 is presented. Following this, the specimens bearing upon diseases of the nervous system are reported, then those of the organs of respiration, circulation, and digestion, making altogether the most valuable and varied contribution to pathology that was ever before collected in a volume of its size. The reports are admirably condensed by the editor, and his notes upon the different pathological conditions are singularly judicious and extremely valuable. Representing as this does the opinions and experience of the leading pathologists of New York upon the different morbid conditions presented, the work cannot fail to interest every practitioner, and be of special value to every earnest and progressive student. Some of the cases related are almost unique, many are exceedingly rare, and all are worthy of permanent record.

While speaking of the general plan of the work, we must not omit reference to two very valuable and exhaustive tabular statements representing the experience of the Society in aneurisms of the aorta and in cancer of the stomach. The first was arranged by Dr. F. Delafield, and includes eighty-four cases; the second by Dr. Bradford S. Thompson, and comprises fifty-five cases. The great satisfaction afforded by the consultation of these tables causes us to wish that there were more of them.

Dr. Peters informs us that the present volume embraces only one-half of the specimens presented during 1875, and that another volume will be required to complete it. Now that a proper initiative is taken by the Society, it is to be hoped that the good work will go on, and that the profession will be favored with equally valuable and interesting volumes as time and circumstance may admit.

Observations on the Diseases of the Rectum. By T. B. Curling, F.R.S.; Consulting Surgeon to the London Hospital, etc. 4th edition revised and enlarged. Lindsay & Blakiston, 1876. 8vo, pp. 244.

The reputation of this work as a practical guide to the surgeon is so well established that it is only necessary to say that the fourth edition is fully equal to any o

its predecessors. The whole volume bears evidence of a very thorough revision; and an entirely new chapter on Colotomy in Congenital Imperfections of the Anus and Rectum is added.

Clinical Studies of Disease in Children. By Eustace Smith, M.D. (Lond.), Fellow of the Royal College of Physicians, etc. Philadelphia: Lindsay & Blakiston, 1876. 12mo, pp. 291.

This little volume is a clinical study of the principal respiratory diseases of children, including acute tuberculosis as it affects the head, chest, and peritoneum. Typical cases are selected and given in detail, with interesting clinical and pathological comments. The first chapter, which is of an introductory character, gives a very succinct and interesting general account of the peculiarities of these diseases in children, following which are chapters devoted respectively to the following topics: Collapse of the lung (post natal atelectasis), croupous pneumonia, pleurisy, acute catarrhal pneumonia, chronic catarrhal pneumonia, fibroid induration of the lung, acute general tuberculosis, acute tuberculosis of the pia mater and tubercular hydrocephalus, and tubercular peritonitis.

As a whole, the work is one of the most valuable contributions to the particular class of infantile diseases of which it treats, to be found in any language.

Atlas of Skin Diseases. By Louis A. Duhring, M.D. Philadelphia: J. B. Lippincott & Co. 1876.

The object of the author of this atlas is to present faithful illustrations of the more common forms of skin affections such as are generally met with in practice, and to delineate as fully as the number of plates —about forty-eight in all—will allow, the phases and varieties of these affections. It will be therefore seen that the work will be of great practical value, as it will afford the opportunity which is usually given to but few, of obtaining a clear knowledge of the diagnostic features of these diseases, which are not as fully understood as they should be. Much of the want of success in the treatment of these affections on the part of the general practitioner, is due to his want of familiarity with them clinically, and the result is that in despair he often declines to adopt any treatment. We think that within the limits of the atlas, as proposed by Dr. Duhring, he will be able to present the appearances of the diseases generally met with, and that from them a clear idea of skin affections generally can be obtained when supplemented by further study and reading. Another important feature of this atlas consists in the fact that diseases as seen in this country only will be portrayed, as it is well known that their general *ensemble* varies within certain limits in different countries. Taking then the fact that the accomplished author proposes to give us illustrations of the more frequent diseases in their varying stages and phases as seen in this country, that they shall be strictly true to nature rather than in part imaginary or diagrammatic, we think that a very decided want will be admirably supplied. Each plate will be accompanied by descriptive letterpress, fully explaining the clinical features shown as well as by directions for treatment. As the present may be judged as a sample, we think the literary part of the work is decidedly valuable. The clinical histories and descriptions are clearly and tersely stated, while the directions for treatment are simple and very satisfactory. In the present fasciculus we have four plates, illustrating erythematous eczema, erythematous lupus, pustular syphilide, and psoriasis. They are of quite uniform merit, though two we think are exceptionally good, namely, the lupus erythematosus and pustular syphilide. Placed in a good light at a short distance from the observer, these plates present appearances nearly like life, and we repeat that their careful study will be very beneficial. We observe in them that the peculiar normal color of the skin is very well imitated, whereas in many of the foreign dermatological plates it is by far too deep, even as representing Austrian skins. If any criticism is made against Dr. Duhring's effort, it is that the redness of the morbid skin is not the exact counterpart of nature. This is noticeable in the plate showing erythematous eczema, an affection well known to be one of the most difficult of illustration. The artists, Messrs. Faber and Moras, have already acquired a deservedly high reputation in this class of work, and we think that Dr. Duhring is fortunate in obtaining their services. We shall look forward with pleasure to the appearance of the succeeding parts, which are to appear quarterly with regularity, knowing that the skill of the author will be again seen in supplying such illustrations as are most needed.

An Introduction to Pathology and Morbid Anatomy. By T. Henry Green, M.D., London. H. C. Lea, Philadelphia. 1876.

We have already reviewed at length this valuable work, and shall now briefly speak of some of the additions in this, the second American from the third London edition. That there was a decided want, owing to the rapid strides made of late years in pathology and morbid anatomy, of a practical and not too large a work on this subject, is well shown by the success obtained by this one. In it we find the various morbid processes carefully described, with an absence of technical details of a confusing nature, and in this point the work is superior to some similar German ones. Inflammation, nutrition, and degeneration are treated of at sufficient length with much clearness. The new formations and tumors also are in general described in a simple and intelligible manner. In this edition the chapter on epithelioma is notably enlarged. Though there is much uniformity of merit of all the chapters, we look upon those relating to the cell, to the changes induced by syphilis, to inflammation of connective tissue, as being very satisfactory. The various inflammations of structures and tissues are carefully treated of, and many illustrations are given. In this edition we find a good chapter on Hodgkin's disease, and that the one on inflammations of the kidneys has been amplified, making a very readable and useful chapter. The work is certainly a peculiarly valuable one, giving as it does in short space the essentials of the subject. It is handsomely gotten up by the American publisher.

Étude sur la Valeur Sémiologique de l'Ecthyma. By Paul Muselier, M.D. Paris: 1876.

In this little work the author gives the results of his studies into the etiology of ecthyma, conducted under the supervision of Prof. Hardy, at Hôpital St. Louis of France. The following conclusions are of interest, and contain essentially the pith of the work:

1st. Ecthyma is an affection rarely idiopathic, almost always secondary.

2d. Acute ecthyma results generally from local causes. It is one of the most frequent and important symptoms of the parasitic diseases.

3d. Chronic ecthyma is due sometimes to external causes, but it is connected always with general causes. The first play the rôle of occasional causes, the others that of predisposing.

4th. Chronic ecthyma is a frequent complication in all conditions of cachexia, chronic diseases, adynamic fevers, debility from bad hygiene. It may develop itself as a critical symptom, or in the course of certain affections of the nervous system.

5th. Ecthyma is one of the most serious cutaneous manifestations of syphilis, its gravity being subordinated to the character of the ulceration, which is only found in those profoundly affected with syphilis, or by bad intercurrent conditions. The supervention of a cachectic condition has a marked influence upon the development and course of syphilitic ecthyma.

THE ANATOMY OF THE HEAD, with Six Lithographic Plates representing frozen Sections of the Head. By THOMAS DWIGHT, M.D., etc. Boston: Hurd, Hough ton & Co. 1876.

DR. DWIGHT has followed the example of Braune in studying anatomy by frozen sections, which are valuable as demonstrations of the relation of parts which dissection generally fails to make clear.

While the neat little volume is not one to be read hurriedly through, it contains a great deal of valuable information in an attractive form for reference, and certainly fills a place in medical literature which has been unoccupied.

The author gives his reasons for producing the book, in his preface, as follows: "Knowledge of anatomy may be compared to that of a city. Many can enumerate the streets crossing the great thoroughfares, can even draw pretty accurate diagrams of the main streets and squares, but be absolutely ignorant of the direction of distant places from one another, and consequently of the short cuts between them, and what is to be encountered on the way. One who knows all this may be said to know the city, and he who can tell what a rod thrust through any part of the body will strike, knows anatomy in its most practical aspect."

Dr. Dwight has made his subject much more attractive and less obscure than it has heretofore been, and he deserves the thanks of all studious medical men.

THE BOOK OF THE BALANCE OF WISDOM, etc. By H. CARRINGTON BOLTON, Ph. D. (Reprint from the American Chemist, May, 1876.) Pp. 30.

THIS pamphlet consists principally of selections from early Arabian writings, and shows that the Arabic philosophers, during and prior to the twelfth century, possessed very great skill in the use of the *balance* and in the determination of *specific gravities*.

LIFE: WHAT DO WE KNOW ABOUT IT? By H. A. JOHNSON, A.M., M.D. Chicago, 1876. Pp. 39.

THE author objects to the positions of Huxley, Tyndall, and other physicists who are studying the metaphysical, and concludes that neither he nor they know much about the matter.

ARGUMENT IN FAVOR OF A CONTAGIOUS DISEASES ACT, etc. By E. T. EASLEY, A.M., M.D. (Reprint from the Rich. and Louisv. Med. Jour. Oct. 1876.) Pp. 32.

AN admirable essay upon the subject, and filled with propositions the truth of which is well recognized by the profession, and which, if conceded by the laity, would lead to speedy legislative action.

THE USE OF THE SPECTROSCOPE. By EMIL ROSENBURG, M.D. (Stevens Triennial Prize Essay.) New York, 1876. G. P. Putnam's Sons. Pp. 68.

THIS essay contains a description of the spectroscope and the method of using it, and chapters upon the characters of the emission and absorption spectra, more particularly of blood, bile and urine, normal and morbid. The medico-legal relations of the subject are also considered. It is decidedly the best contribution (in the English language) to the subject of spectroscopy, so far as it relates to matters of interest to the physiologist and physician, that has yet appeared.

MICRO-PHOTOGRAPHS IN HISTOLOGY. By CARL SEILER, M.D. Parts III., IV. and V. Philadelphia: J. H. Coates & Co.

As in previous issues, some of the plates are good, others are wretched. Plate XV. of blood-corpuscles of man and of the ox is a valuable contribution to the question that is just now agitating the minds of Drs. Richardson and Woodward; the former claiming that under certain circumstances it is possible to distinguish microscopically between the blood of man and certain mammals, while Dr. W. shows that under certain other circumstances this is impossible. Plate XXII., representing the kidney of a mouse, is capital; but the work as a whole is not what it should be, and does not fairly represent American photo-micrographic capabilities.

A SYNOPSIS OF DERMATOLOGY. Compiled by F. M. BLODGETT, M.D. Boston: James Campbell. 1876.

THIS is a chart containing Hebra's and Piffard's classifications; White's statistics of cutaneous diseases in Boston; profile drawings of the principal skin lesions, after Piffard; and the usual seats of disease, according to Tilbury Fox. The chart will prove of value to the student, as it gives him at a glance much useful elementary information.

A TREATISE ON THE THEORY AND PRACTICE OF MEDICINE, by JOHN SYER BRISTOWE, M.D. Lond., F.R.C.P.; Physician to St. Thomas's Hospital, etc., etc. Edited, with Notes, by James H. Hutchinson, M.D., one of the attending Physicians to the Pennsylvania Hospital, etc. Philadelphia: H. C. Lea. 1876. 8vo, pp. 1089.

THE number of new books on the practice of medicine is getting to be so great, and the facts which they contain are generally so well established, that it is quite difficult for the reviewer to point out any very distinctive characteristics. So few authors in this department of medicine have any original views to offer, that their works cannot be distinguished in that particular from the general run of ordinary treatises. We can say, perhaps, in summing up the whole matter, that because such works are up to the times, are ordinarily comprehensive in scope, that they are to serve a useful purpose. How an ordinary student can satisfy himself which is the one which will best suit his necessities is a very difficult question to decide. We must admit that each author has his peculiarities of presentation of his subject, method of arrangement, in fact system of teaching, which can only be referred to in general terms. In the present instance the notable feature of the work before us is its extraordinary scope of subjects, putting one in mind of times gone by, when medicine was divided into two great departments—that of medicine proper, and surgery; that what could not be comprised in the latter must find a place in the former. In this respect this work may be considered as a type of an encyclopædal manual for the guide of the practitioner, who must forsooth content himself with one book on practice in which every disease which he is liable to meet is described and treated. Considering the size of the work, granting what has already been said of its scope, the reader will be prepared to expect great conciseness, and will not be disappointed.

THE PHYSICIAN'S VISITING LIST for 1877. Philadelphia: Lindsay & Blakiston. 1877.

As frequently said on former occasions, this list has the two great advantages of simplicity and convenience, which must always maintain its place as a favorite.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, December 11, 1876.

DR. JOHN C. PETERS, PRESIDENT, IN THE CHAIR.

THE PROPER TREATMENT FOR LACERATION OF THE CERVIX UTERI.

DR. EMMET'S paper being before the Society for discussion (*vid.* page 823).

DR. FORDYCE BARKER remarked that when Dr. Emmet read his first paper upon the subject under consideration, although he could recognize the condition described, and had the fullest faith in the truth and accuracy of the statement made, he was not able to understand it sufficiently to accept the views which the author of the paper then presented. Since that time he had become a convert to Dr. Emmet's views upon the subject, and had come to regard his contribution as one of great importance to gynecology.

Special reference was made to a case which Dr. Emmet had given him the opportunity to see, in which the uterus measured five inches, with a cervix very much enlarged, and presenting the angry, eroded, patulous, everted appearance precisely as described in the paper. The preparatory treatment was thoroughly carried out, the operation performed, and, having since had the opportunity of making an examination, he had found the uterus to measure only 2½ inches, and the cervix presented the appearance of that of the nulliparous woman. That such would be the result when the treatment, preparatory, operative, and subsequent, was carried out with the carefulness of detail insisted upon by Dr. Emmet, there was no doubt. In the instance referred to, the cervix presented no appearance of having been subjected to an operation.

With reference to cicatrices which resulted from the operation, Dr. Barker believed that they would entirely disappear in most cases, while the cicatricial tissue which resulted from the effort nature made to effect a recovery remained indurated, and became a serious disturbing element in the subsequent history of the case.

It was maintained that this peculiarity would enable the examiner to determine whether the laceration, if cured, had been cured by an operation or by spontaneous union.

Dr. Barker further remarked that he had seen but few cases of laceration of the cervix in later years, and explained that fact upon the ground that those who were in the better condition in society had competent obstetrical attendants during the time of parturition and throughout the puerperal period. Those not in a social condition to obtain such attention, as a general thing, arose from their beds too early after confinement, and the result was that spontaneous union of the laceration, if it was to occur, was prevented, and the general disturbance to which it gave rise soon followed. It was for that reason the injury was more commonly seen in the poorer class of patients.

Dr. Barker was not quite certain as to whether Dr. Emmet believed the arrest of involution and the subsequent erosion, version of the uterus, etc., were primarily due to laceration of the cervix, or whether it was the subinvolution which prevented spontaneous union of the laceration, the laceration not necessarily bearing the relation of cause to all the other conditions developed.

He believed that laceration took place and even became perfect during the puerperal period; for when the woman was kept in bed the parts were placed in a favorable position for coaptation of the edges of the wound, and the weight of the organ did not give rise to eversion of the cervix and prevent union.

Reference was then made to cases which formerly came under his care in Bellevue Hospital, and in which the uterus was found increased in size, displaced as a matter of course, cervix eroded, eversion was not recognized—in short, the cervix presented the appearance described by Dr. Emmet in his paper; but the patients were relieved by treatment, and passed from under observation. It was a noticeable fact, however, that those patients returned, and would pass through the same course of treatment, or essentially the same, and go out again. Those cases were cured most commonly by the use of the actual cautery. The actual cautery entirely destroyed the condition described as cystic degeneration of the mucous follicles of the cervix. None of the caustics in ordinary use seemed to affect these to any great extent; but the actual cautery so destroyed them and modified the nutrition of the parts that their cure was effected. It was formerly urged as an objection to the use of the actual cautery that it would leave behind it cicatricial tissue, which might interfere with the process of parturition. That result Dr. Barker had never seen, but, on the contrary, he had seen just the opposite state of affairs, and related a case in which the actual cautery had been used freely, and in a subsequent labor the child was born before the obstetrician arrived.

The former papers read by Dr. Emmet had been of great service in calling attention to the effects produced upon the nervous system in consequence of the contraction of cicatricial tissue upon and about the cervix uteri and at other situations upon the genito-urinary organs of the female. That fact was one now commonly recognized; but Dr. Barker had not seen it referred to, that cicatricial tissue, after an operation, was absorbed; hence, gave no rise to subsequent trouble. He had seen cicatricial tissue left as the result of improper use of caustics.

With regard to the success of the operation performed by Dr. Emmet, it depended entirely upon carrying out fully the *minor details* of the preparatory treatment, of the operation itself, and of the subsequent treatment.

DR. PEASLEE, in alluding to some of the reasons for the operation, called attention to the noticeable fact that, if but one laceration was present, it was almost always upon the left side. That fact was explained by reason of the greater frequency with which the fœtus presented in the first position, consequently a greater strain was brought upon that portion of the os uteri. Laceration of the cervix occurred occasionally upon the right side alone, and the probable explanation was, that the second instead of the first position was occupied by the presenting part of the child.

With regard to diagnosis, if the laceration was upon one side only, perhaps was originally double, and had healed upon the right side, unless one was familiar with the appearance presented by the parts, it was not easy to make out. On that account many cases escaped attention. Dr. Peaslee maintained that the number of cases was great beyond all conception, except to him who had given special attention to that

class of affections. Until very recently the exact condition had not been recognized at all, and the first recognition, or at least the first description, was given by Dr. Emmet. There were many eminent gynecologists, and even eminent authors, who did not yet know what the cases were. Did they fully understand them, they would not speak of a peculiar kind of ulceration which results from parturition. No author had a right, in the light of the knowledge now within reach, to speak in such an indefinite manner of any class of cases, but especially of that class which had been so clearly described by Dr. Emmet.

With regard to frequency, he could say that scarcely a case of ruptured perineum occurred without laceration of the cervix, and probably from one side to the other. Sometimes such laceration occurred without any laceration at all of the perineum.

Why had not this class of cases been found out before? It was probably because the injury had interfered with involution, and the case had seemed to be one of hypertrophy; that is, there had seemed to be only an actual increase in size of the cervix, and the os had been found to be of a peculiar shape and size with two surfaces, one in front and the other behind, covered with enlarged papillæ, called granulations, and presenting that red, angry looking appearance. The cervix, however, was all there, and when turned up it would be found that those angry-looking surfaces were nothing more nor less than the lining membrane belonging originally to the internal surface of the canal of the cervix.

Why did the operation become necessary?

In the first place, a laceration up to the vaginal junction prevented complete involution in a majority of cases, because the two lips of the wound became separated entirely, and the cervical canal became so far everted that constant irritation of the surfaces was kept up, which sustained a continuous congestion of the uterus, and rendered farther involution impossible.

But not every case had associated with it subinvolution of the uterus, the uterine cavity being too long and too large; but the cervix alone might be affected. If there was double laceration and either side had healed spontaneously, hypertrophy of the cervix would remain. There was not only an erosion of the surfaces of the flaps, but a growth of the anterior and posterior lips.

The laceration, then, not only arrested the process of involution, but gradually produced hypertrophy of the cervix, and it was in addition one of the most certain causes of sterility. For the removal of the latter condition the operation was a proper one to be performed. But there were cases, as well, which required the operation even after the menopause. When the laceration had healed upon one side, it did not interfere so much with involution, but it would interfere with pregnancy.

With regard to the operation itself, there were, as a rule, no traces of it left. Uterine tissue, in common with all unvoluntary muscular fibre, healed more rapidly than any other tissue, and the appearance of the cervix after the operation was almost perfectly normal.

Dr. Peaslee then referred to a case in which the cervix measured seven inches in circumference before the operation, but at the end of three months presented an appearance almost entirely normal. With regard to the sutures he had commonly permitted them to remain more than a week, and had had no difficulty in removing them without affecting the union of the parts. By taking deep sutures it was believed to be safe to leave them sufficiently long to allow adhesion to become so firm that their removal could be effected without endangering the union of the flaps.

Dr. Pallen believed that laceration of the cervix was very frequent, full forty per cent. of the cases at the clinic at the University Medical College presenting that lesion. He regarded the diagnosis as easy by the touch alone; and when the patient was placed upon the left side, a Sims speculum employed, and the parts raised with a tenaculum, the fissure could be readily recognized. Coaptation of the torn surfaces by means of sutures was held to be the best method of treatment, either for immediate relief or as a subsequent operation. Cure without surgical procedure was regarded as rare; and the operation rarely, if ever, failed to bring about the integrity of the cervix. Dr. Pallen had performed the operation during the past ten years substantially as Dr. Emmet had recommended, and read extracts from papers in illustration of the views he held at the beginning of that period.

Dr. Downs raised the question whether occlusion of the os might not occur as the result of spontaneous or operative closure of the flaps of a lacerated cervix, and cited a case which seemed to him to illustrate that possibility.

Dr. Mundé presented some statistics regarding the frequency of laceration of the cervix. Out of 490 uterine cases treated by him at Mount Sinai Hospital there were 28 in which complete laceration, bilateral or otherwise, had occurred, or $5\frac{5}{7}$ per cent. That was a smaller percentage than Dr. Hanks had reported from Demilt Dispensary, or $8\frac{4}{10}$ per cent., and considerably less than mentioned by Dr. Pallen. Of those 28 cases, 23 were bilateral, 4 unilateral, and 1 posterior. Sixteen were attended with endo-cervicitis or metritis, and there was usually subinvolution or hyperplasia. Eleven were connected with displacement or hyperplasia, with uterine catarrh. One case exhibited no uterine symptoms whatever, and no other disease of the uterus. The more eversion there was present, the more marked were the symptoms. In some cases there was no eversion, but simply laceration, and yet there was present considerable endo-cervicitis. He had also found that when treated by ordinary local measures, without operation, they would get better, and remain away for a time, but return with the same trouble as bad as ever.

Dr. Hanks remarked that one point should perhaps be made more prominent, and that was with reference to cicatricial tissue remaining after the operation. He was of the opinion that it was a peculiarity of the operation that no cicatricial tissue remained, and cited a case in which labor had subsequently occurred without the slightest difficulty, and was effected without laceration being reproduced. Dr. Hanks also drew attention to the use of a double tenaculum for holding the lips of the wound together, thus permitting of the more easy introduction of the sutures by less skilful hands than Dr. Emmet's.

Dr. Chamberlain referred to the fact that he had failed for a long time to recognize the lesion, although constantly seeing cases in which it was present. The reason for not recognizing the condition he attributed to the fact that he used the Ferguson speculum, by which it was obscured. By the use of the Sims speculum, or its equivalent, he had been able to detect its existence when unable to recognize it by means of the Ferguson instrument.

Dr. Gillette regarded the diagnosis as very simple, and the mechanical operation as one easily performed. His first operations had been failures because of insufficient instruction concerning preparatory treatment.

The degree of displacement, the cystic degeneration of the tissues, and the congested condition, were not fully considered by him formerly, hence failure followed his operations. That had been the experience of others, and probably such experience had been due to an equally insufficient knowledge as possessed by himself.

Dr. Otis remarked that for several years he had had opportunity of observing the results following the division of cicatricial tissue in canals of similar character, especially the urethra, and had found it to be an invariable result that, when the constriction was thoroughly divided, the cicatricial tissue was entirely absorbed. He had also observed that where division had been made across the urethra, the same result did not follow. In order to produce stricture the injury must extend around the canal, which it did not do where the incision was made longitudinally. In such case the cicatricial deposit had no hold around the canal, but the contraction was upon the cicatricial tissue itself, and it was finally able to disappear; whereas, if the plastic deposit had surrounded the canal, the contraction took place at the expense of the canal.

Dr. Wylie remarked that he had had the opportunity of observing the results which had followed closing of laceration of the cervix by means of sutures, at the Woman's Hospital, and had not seen any subquent bad results. It had seemed that the condition was not yet recognized by some eminent gynecologists, for a case had come under his observation which had been regarded by several gentlemen in Philadelphia as one of cancer of the cervix, but which, after careful examination, was recognized as one of simple laceration, and completely cured by an operation performed by Dr. Emmet.

The Society then adjourned.

Correspondence.

A NEW METHOD OF ADMINISTERING QUININE.

To the Editor of The Medical Record.

Allow me to say a few words recommending a new medicine to our already long list.

In the October number of the *American Journal of Medical Sciences* of the present year is an article by Fothergill, of London, recommending the hydrobromic acid. Among other properties he speaks of it as a solvent for quinine and a preventive of the head symptoms resulting from the use of quinine.

We had a patient in the hospital with chronic malaria, who could not take quinine for any length of time without being "almost crazy from it," as she expressed herself, and at the suggestion of Dr. Burrall, the visiting physician, we tested the acid on this case.

It was given in ℥ ss. doses, with quinine in capsules, and with the happiest result. The roaring in the ears and the dizziness disappeared, and the patient no longer objected to being cured by quinine.

Since then, I have tested the medicine in many cases, and it has never failed. Dr. H., of Washington, D. C., entered the hospital suffering from malarial poisoning and from large doses of quinine, and was much pleased at being relieved from the cinchonism by the acid. The tinnitus aurium following the exhibition of quinine seems to be due to an active congestion of at least some parts, if not the whole of the brain, as Dr. D. B St. J. Roosa has observed that after taking ten or fifteen grains of quinine the membrana tympani and malleus are markedly injected. It had before been noticed that the administration of quinine aggravated the symptoms of otitis media and other aural affections.

It may be that hydrobromic acid, being analogous to bromide of potassium, may, like bromide of potassium, cause contraction of the blood-vessels, and thus prevent the bad effects of quinine. However this may be, it acts in the happiest manner.

There is a growing mistrust among the laity towards quinine. All sorts of stories are reported concerning its harmful effects, such as causing permanent deafness, impairing the eyesight, affecting the brain, etc., etc. Nor are these opinions wholly without reason, for the roaring in the ears, the dizziness, the trembling limbs, the sensation of being in a storm at sea generally, is anything but pleasant and reassuring to a person distrustful of "allopathy." It is then the duty of the profession to keep our faithful ally quinine from falling into disrepute when it can be done by so simple a means as the use of this acid.

In giving quinine in solution, I use the following formula:

℞. Quinine sulph. . . . . ℥ j.
Hydrobromic acid,
Aquæ. . . . . āā ℥ iss.
M. Sig.—Two teaspoonfuls contain five grains of quinine.

You can insert the formula for making the acid according to Fothergill, if you see fit.

Dissolve ℥ x., ℥ vj., grs. xxviij. of potassæ bromidi in water Oiv., add ℥ xiij., ℥ i., grs. xxxvij. of tartaric acid. The *acid remains in solution*, and potassa bitartrate is precipitated.

Resident Physician, Presbyterian Hospital.

ANTISEPTIC OVARIOTOMY.

To the Editor of The Medical Record.

My dear Sir:—In the number of the Record for Dec. 9, 1876, I find a case of ovariotomy reported by J. Marion Sims, M.D., in which "Lister's antiseptic method" was employed.

I desire to call attention to the following quotation from that article. The italics are my own. "The operation was done on Thursday, *the 23d November last. I am particular in fixing the date, because I believe it inaugurates a new departure in ovariotomy.*"

From a perusal of this and the context, the inference to be drawn is, that the 23d day of November, 1876, marked the *first* employment of "Lister's antiseptic method" in the performance of ovariotomy.

I take the liberty of forwarding to you an extract from a report of my own, published in the *Homœopathic Times* for November, 1876, bearing this title: "Successful Ovariotomy — Antiseptic Treatment," which, I think, may place the date of the employment of "Lister's method" in ovariotomy, six months prior to the date mentioned in the article of Dr. Sims.

After some general remarks on the condition of the patient and the history of the case, the article reads:

"On May 24th I proceeded to remove the tumor, which was unilocular.

"*Having had the apartment thoroughly aired, the atmosphere of the room was charged with carbolic acid spray*—from a solution in the proportion of about one part of the acid to fifty of water. *The table was also sprayed, and my hands washed in a carbolic acid solution.* She was brought under the anæsthetic without

trouble. An incision, not more than two and a half inches in length, was made in the linea alba, and the tumor exposed. The fluid drawn off was dark brown in color, with flocculi here and there deposited through it. The adhesions were quite numerous, but *not* dense, and the vessels were secured by torsion *and Lister's antiseptic animal ligatures*, the ends being cut off close, and returned to the abdominal cavity. The pedicle, which was broad, was tied *with a strong animal ligature*, passed double through its centre, and secured on both sides. The écraseur was then applied, and the pedicle severed. The ends of the ligature were cut close, and the stump dropped back into the abdomen. *The parts were sprayed constantly with carbolic acid, and the sponges used were soaked in a solution of* $\frac{1}{20}$ *proportion of acid.* Silver wire sutures were employed to close the wound, and the patient put to bed after a compress saturated *with carbolic acid solution had been applied, and a bandage placed around the abdomen.*"

This patient recovered without a single untoward symptom, and the tumor weighed about 23 lbs. The ligatures used for the pedicle and to arrest the hemorrhage were prepared by J. H. McFarlan & Co.,' London, after Lister's formula. I might here also mention that on the 18th of March, nearly two months before the operation just mentioned, I removed a remarkable dermoid cyst, containing teeth, bones of various and peculiar shape, tufts of hair, quantities of lime and colloid substance, in which operation the antiseptic method was used, not, however, in so thorough a manner as in the case quoted. In the latter the parts were sprayed before and after the operation, and my hands dipped in artificial serum impregnated with carbolic acid. The pedicle was ligated as were the vessels—which were numerous—with Lister's carbolized catgut. The patient died on the fifth day. At the post-mortem examination the condition of the pedicle and vessels was so satisfactory, that I believe ere long, that clamp twine, or wire, will be cast aside, and antiseptic animal ligatures be used entirely in the treatment of the pedicle.

Very truly yours,

WM. TOD HELMUTH.

21 West Thirty-seventh Street, New York,
Dec. 9, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Dec. 10th to Dec. 16th, 1876.

COOPER, GEO. E., Major and Surgeon. Appointed Assistant Medical Purveyor, with the rank of Lieutenant-Colonel, to date from Dec. 2, 1876; *vice* Laub, deceased.

BILLINGS, J. S., Asst.-Surgeon. Promoted Surgeon, with the rank of Major, to date from Dec. 2, 1876; *vice* Cooper, appointed Asst. Medical Purveyor.

EXPECTANT TREATMENT OF CHOREA.—Doctors E. B. Gray and H. M. Tuckwell gave, some five years ago, a series of cases treated in this manner. They now present twenty more cases where they were treated in isolated wards, had good nursing, large and well-padded cribs, plenty of nutritious food, but no stimulants. The average duration of these twenty cases of chorea was a little over nine weeks. The doctors are inclined to rely upon this treatment till more conclusive evidence can be obtained that the disease is in the slightest degree favorably influenced by medicines. —*The Lancet*, November 18, 1876.

MUTUAL DISSECTION.—A society has been formed in Paris, having for the object the dissection of deceased members by the survivors. The youngest member will doubtless have excellent facilities for the study of practical anatomy at a nominal price.

MEDICAL SUPERVISION IN SCHOOLS.—The *Cincinnati Lancet and Observer*, in commenting upon our recent editorial, very properly says: "It would be a wise action on the part of every Board of Education in large cities to appoint a committee to report upon the advisability of appointing a medical inspection of schools."

CHICAGO is in a bad way in consequence of an inefficient Health Board, at least so we learn from an editorial in the last issue of the *Chicago Medical Examiner*.

LADY VISITORS TO MEDICAL SOCIETIES.—The Medical Society of London declines, by vote, to admit lady (medical) visitors to its meetings.

MIASMATIC ALGÆ.—MM. Lanzi and G. Terrigi have published at Rome an account of observations on the microscopic fauna and flora of the marshes in the Campagna, and endeavor to show that there is a connection between the product of changes in the cells of certain algæ and the cause of malarial fever. Dark granules form in the cells, which at last they fill, and then the algæ rot. They cultivated the plants in an aquarium, and followed the process in all its stages. The algæ develop in the marshes which are formed in winter and spring. When the moisture disappears under the heat of summer, the surface of the ground is left covered by a layer of stinking algæ. The same conditions are found, although not to the same extent, even where there are no marshes, the uncultivated ground being covered more or less with putrefying vegetable matter. The authors believe that the dark granules act as a ferment. They are found in the atmospheric dust of the Campagna, from which they can be developed abundantly by cultivation. Lanzi believes that they are identical with the pigmented sphærobacteria of Cohn and the bacteridium brunneum of Schroetter. The authors assert that the pigment-granules found in the liver and spleen of persons who have suffered from malarial cachexia are similar to the granules from the algæ cells; and Lanzi affirms the identity of the malaria melanin of pathological anatomists with the granules which result from the decomposition of these plants. The germs were found in the atmosphere of the Campagna to a height of fifty centimetres above the surface of the marshy soil. Lanzi found abundantly malaria-melanin in the liver and spleen of guinea-pigs which had breathed for a considerable time air of the marshes which contained these organisms.—*British Medical Journal.*

SELECTED CASES OF HYPERTROPHIED GLANDULAR TISSUE OF THE VAULT OF THE PHARYNX AND OTHER HYPERTROPHIED TISSUE OF THE NASAL PASSAGES,

WITH SYMPTOMS OF POST-NASAL AND NASAL CATARRH, CURED WITH THE GALVANO-CAUTERY; TOGETHER WITH REMARKS AND DESCRIPTION OF AN INSTRUMENT.

By R. P. LINCOLN, M.D.,

NEW YORK.

Miss C., aged twenty-one years, was referred to me for treatment, February, 1865. She was in good general health, of a nervous, vivacious disposition, and had inherited no unfavorable diserasia. Much time had been devoted to her musical education, especially vocal, in which exceptional proficiency had been attained.

For the past two years a hoarseness, attributed originally to a cold, has been a frequent and finally an almost constant cause of annoyance. At the same time a want of timbre in the head-notes was also observed, and a nasal character in ordinary enunciation. At first, efforts to clear the throat afforded temporary relief of the hoarseness, but in a short time the deadened consonant sounds were unvarying. To breathe through the nostrils required special attention, while at night it was only practicable to breathe through the open mouth. A disagreeable naso-pharyngeal discharge and an occasional hacking cough were also complained of.

On inspecting the pharynx, transparent mucus was found flowing from above, and its mucous membrane a little congested and thickened, greater above than below. A similar condition was exposed in the larynx by the mirror, and in addition, in the naso-pharyngeal space, an excessive hypertrophy of the adenoid tissue of the vault. This enlargement occluded at least three-fourths of the opening of the posterior nares, and was covered with tenacious mucus.

The anterior nares were also much obstructed by submucous thickening, especially over the inferior turbinated bones, and from them a ropy mucus was discharged.

Nothing abnormal existed in the lungs, and all other functions were well performed.

The patient had submitted to a great variety of treatment, both internal and local, without material benefit.

Treatment was advised as follows: destruction of the adenoid tissue by means of the galvano-cautery, and of the polypoid growths in the nostrils by chromic acid, and subsequently spray applications of astringent solutions to the naso-pharyngeal tract and interior of the larynx.

The use of the galvano-cautery was declined, and a trial of the chromic acid desired. Seven applications of the latter were made to the growths in the vault of the pharynx, and three to the enlargement in the anterior nares, at intervals of from three to five days.

The nasal thickening was thus thoroughly removed, but in the post-nasal region but little was accomplished, the tissue being unusually firm. My first recommendation was now yielded to, and three applications of the galvano-cautery, at intervals of a week, completely removed the remaining glandular tissue.

A few applications of a spray of tannin, glycerine and carbolic acid and water accomplished the removal of every evidence of disease, and relief of all the symptoms complained of.

Miss B., aged 14 years, a pupil in one of our public schools, was brought to me by her mother, November, 1875, who was much depressed because, as she said, of the growing stupidity of her daughter. The patient was found to have had more or less trouble with her throat since an attack of scarlet fever when two years of age. She now had a slight cough, or, more properly, was frequently compelled to clear her throat; but the principal cause of complaint was a defective enunciation; this was a source of annoyance to herself and trial to her teachers, which no amount of patient practice had been able to correct. Her general health was good, though she often suffered from sore throat. Her breathing was chiefly oral, yet there was no nasal catarrh complained of, and though the nose itself was apparently small, the nasal mucous membrane was normal in appearance.

On inspection through the mouth, both tonsils were found greatly enlarged, and on using the mirror the adenoid tissue of the vault was seen nearly to fill it; from the latter mucus was flowing down the pharynx, and caused the cough that was complained of.

Excision of the tonsils and the use of the galvano-cautery on the adenoid tissue were urged. The first was not permitted; their removal, however, was undertaken by means of Vienna paste, and accomplished after four applications to each gland at an interval of four or five days. Two applications with the galvano-cautery, with an interval of a week, completely removed the hypertrophied tissue above, and effected a complete cure.

James B., aged sixteen years, of French extraction and scrofulous diathesis, but fairly nourished, came under my care March, 1876. For more than four years he had been troubled by a naso-pharyngeal catarrh, and was very subject to sore throat and "colds." For the past year his trouble had become excessive, but as yet he had had no special treatment. Formerly a bright, intelligent lad, he had become mentally dull, and wore a characteristic stupid expression, and was looked upon by his teachers with pity and indulgence. His voice was dull, thick, and lacked flexibility, and his breathing almost entirely through his open mouth. The sense of smell had gradually disappeared, while that of hearing was so defective that the tick of my watch was heard only when held within an inch of either ear. On examining the nostrils they were found swollen, and from them poured a profuse muco-purulent discharge; the same conditions presented in the pharynx, while by means of the mirror, the naso-pharyngeal space was found quite filled by hypertrophied glandular tissue.

Both tympana were concave and dull, but readily restored temporarily by practising Politzer's method of inflation.

After removing the secretion from the adenoid tissue a thorough application was made to it with the galvano-cautery, and to the nostrils and pharynx a spray of a solution containing three grains chromic acid, ten grains bichromate of potash in an ounce of water. At the expiration of a week the galvano-cautery was again used as before, and at the same seance a galvano-cautery needle was introduced well into the infiltrated tissue in the nostrils. It was two weeks before the eschar had entirely come away and the wounds healed, but the defective enunciation and the embarrassed breathing were already corrected. Extending over a period of two weeks longer, at intervals of

about three days, applications of the spray and Politzer's method of inflation were practised, when the patient was discharged, cured of every evidence of disease in the naso-pharyngeal region.

The only internal treatment employed was during the last ten days, when, on account of a succession of boils, the following was prescribed:

℞. Potassii iodidi..... ʒ ss.
Ferri pyrophosphatis..... ʒ i.
Syrupi simplicis,
Aquæ..... āā ʒ ij.
M. Sig.—Take one teaspoonful after meals.

Remarks.—Since the invention of the rhinoscope, and Dr. Wm. Meyer's effort to direct the attention of the profession to the frequency of the hypertrophied glandular tissue in the posterior nasal region, its influence in producing organic and functional changes in the conditions and uses of the upper air-passages is acknowledged. Yet I doubt that the important part exercised by these growths in many cases of disease in the upper-air passages has received the consideration it deserves, and I am sustained in my belief by the frequency with which I have met these growths during the past eight years, and by the infrequency of references to them in medical periodicals and the brief notice of them in special works.

Dr. Wm. Meyer met with the disease 102 times in his private practice in the course of eighteen months; and of 2,000 pupils in the public schools of Copenhagen examined by him, 20 cases were discovered. Prof. Cohen has a reasonable doubt of the accuracy of Meyer's diagnosis, for he seems to have relied chiefly on digital exploration; his leading symptom—a sensation as of a bundle of earth-worms—being almost always suggested by the constriction upon the finger of the soft parts of this region by its muscles, may have been easily misinterpreted. At the same time it should be remembered that the climate of Copenhagen is probably more conducive to the development of this disease than our own. Whatever the verdict, the affection is not uncommon with us, and the above cases are reported not because they may be considered typical in their history, but chiefly to illustrate the success of treatment.

Formerly, in the management of these cases I relied on nitrate of silver, chromic acid, Vienna paste, or the curette, as prepared by Meyer; but two years ago devised an instrument by means of which I could conveniently use the galvano-cautery, and which has superseded in my practice the other methods when this is practical.

Its advantages are, its radical effectiveness, shortness of treatment—two or three applications being sufficient to remove the most extensive growths—and its comparative painlessness.

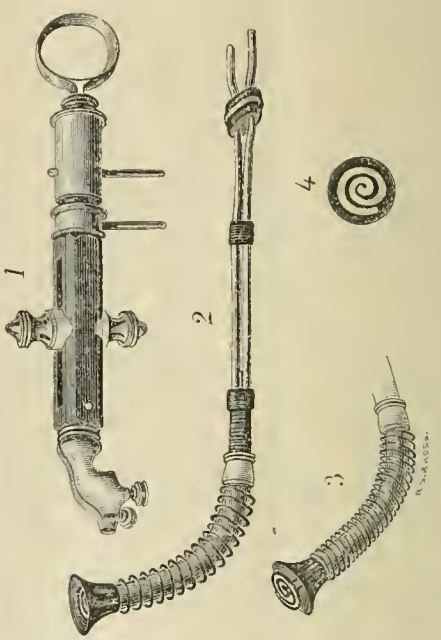
In respect to the latter feature, I can assert as a result of my experience in many cases, and as was testified to by the subject of the first case in this report, in the presence of several physicians who witnessed the operation, that there was less pain either immediately at or subsequent to the application than after the use of escharotics.

The only requisites are, the docility of the patient, and if an anæsthetic is permissible this is always secured, and a suitable battery and electrode.

In the last of the above cases, and in similar subsequent operations, I have made use of Dawson's battery, and have found it to fulfil every indication of a cautery battery.

The electrode used was made at my suggestion, for use in the naso-pharyngeal region in another affection, by Otto & Reynders, though afterwards somewhat modified. It consists of an addition to one of Leiter's electrodes, and used with his universal handle, all of which is figured herewith.

In some cases the shield described below may be dispensed with, either on account of the patient being able to avoid contraction of the palate during an operation, or when it can be controlled by some retractor, as the rubber cord suggested by Dr. Wales.



1. Leiter's universal handle.
2. Electrode, on which is fixed a spiral spring terminating in a shield of bone concealing a platina disk which terminates the electrode.
3. The same, with the disk disclosed by the recession of the shield when pressed against the tissues in the act of cauterization. The shield serves to protect the surrounding parts in case the instrument is grasped by them during an operation.
4. The disk in its relation with the shield.

The above figures are one-half the size of the original.

EDGEWISE DISLOCATION OF THE PATELLA.

By ALEXANDER N. DOUGHERTY, M.D.,

NEWARK, N. J.

This day, Dec 4, 1876, I was summoned to see a young man named Leonard, who, while working as a painter on the roof of a house, had met with a singular hurt about the knee.

I found him in the attic of the house where the accident occurred. The left lower extremity (the one involved) was in a state of extreme extension, and the patella was tilted up on its inner edge, the posterior surface of the bone looking directly outward, and the exterior tendon correspondingly tilted up and stretched. The patient seemed in great pain, which any attempt at reduction much augmented. I had him laid down on a bed, and after a few minutes of manipulation, during which he called loudly for chloroform, I succeeded in effecting reduction, which took place with an audible snap.

The manipulation consisted in depressing, with a joggling motion, the projecting edge towards the outer condyle. This failed at first, but after a few

trials proved effectual. The thigh was not flexed, as recommended by Gross.

The cause of the accident seemed to be a sudden wrench of the knee in turning the body while the foot was lodged in the gutter of the roof.

Gross speaks of his having encountered only thirteen recorded cases. Mine will make a fourteenth, unless he has seen others since the publication of his book—which is, by the way, in my judgment, the most complete and valuable treatise on surgery extant in any language. He says, p. 87, vol. ii.: "The reduction is generally extremely difficult, owing, apparently, to the trouble which is experienced in disengaging the bone from the sub-condyloid fossa where it is almost as firmly impacted as if it were screwed fast. On several occasions, indeed, the most violent efforts, conjoined with the division of the ligament of the patella, were hardly sufficient to accomplish the object. . . . . Fortunately, such measures are not likely to be again repeated, since experience has fully shown not only their utter inefficiency, but great danger.

"The proper method of reduction consists in flexing the thigh strongly upon the pelvis, and in bending the leg forcibly to the fullest extent upon the thigh, the limb being again immediately brought into a straight line, at the same time that an effort is made to push the bone strongly over towards the inner part of the joint."

He disapproves of the extended position of the limb in connection with efforts at reduction, but my case shows that it may answer equally well on occasion.

I ordered the use of an elastic cap; and next day I found my patient walking on the street so equipped, and suffering no inconvenience from his accident.

A CLINICAL CONTRIBUTION TO THE EFFECTS OF ACUTE BROMIZATION.

By GEORGE M. SCHWEIG, M.D.,
NEW YORK.

The remarks I have to offer are based chiefly, though not wholly, on observations made recently (April, 1876) in a case of morphine methomania, where I administered various salts of bromine in a manner that I shall presently describe. The deductions that I have drawn from the effects as observed, are borne out by similar, though less characteristic effects obtained in two other cases, to which I shall have occasion to recur hereinafter.

It would be foreign to the purpose of the present paper to give in full the history of the patients, or any more of it than may have a bearing on the effects to be considered.

Case. I.—Mr. S., æt. 42, married, came to consult me, March 24, 1876, accompanied by his attending physician. The object of his visit was to be cured of the morphia habit. As necessary to a proper appreciation of his then physical condition, I will state the following: He had been addicted to morphia for about seven years, during the last four of which he had used it hypodermically. The doses during this period had ranged from grm. .048 to .516 (¾ to 8 grains) per diem, and were for a short time as high as 1.0 (15½ grains). He had been twice at the Asylum in Binghamton; the last time (in 1875) for nearly four months; had obtained no relief. A brief forced abstinence had produced delirium and mania, followed by an increased consumption of the drug. The habit had been engendered by the therapeutic administration of morphia for the relief of gastralgia (probably hysterical). His condition, as when I first saw him, can be summed up in a few words. He had:

1. *Morphia methomania*, the average daily (hypodermic) consumption being .064 (one grain), taken in two doses.
2. *Hysteria*, its manifestations limited to the solar plexus.
3. Symptoms of the first stage of *locomotor ataxia*.
4. *Urethral stricture*.

After some preparatory treatment, such as dilating the stricture, administering tonics, etc., as also an unsuccessful attempt to decrease his daily allowance of morphia, the bromide treatment was instituted as follows: April 5th.—Bedtime, potass. bromid., grammes 2.0 (ʒ ss.). April 6th.—6 A.M., pot. bromid., 2.0; 7 A.M., 2.0; 7.30, being very restless, solut. Magend. ♏ v. hypoderm.; 2.0 pot. bromid. at 9.30 and 11 A.M., 12 M. and 12.30 P.M.; at 12.45, ♏ iij. Magend. sol., by skin; then resumed bromide as follows: 2.0 at 1, 1.35, 2.15, 3, 3.30, 4.30, 5.20, and 6.10 P.M. Then changed to bromide of sodium, of which 2.0 was given at 6.45. He now for the first time during the treatment began to show signs of somnolence. 7.15, sod. brom., 2.0; slept for three hours, when, at 10.20, dose was repeated. Slept to April 7th, 4.30 A.M., when treatment was resumed as follows: 2.0 sod. bromid., at 4.30, 5, 5.40 (very restless; 5 ♏ Magend. sol. by skin), and 7.10 A.M.; fell asleep shortly after last dose. Slept 5½ hours, when treatment was again resumed with 2.0 doses of the salt at 1.20, 2.20, 3.40, 4 (at 4.10, being very restless, received ♏ v. Magend. sol.), 4.30, 5, 5.30, and 7.30 P.M. Bromide of calcium was now substituted for the sodium, and given as follows: 10 P.M., 4.0 (ʒ i); 10.30, 2.0; same at 12, night. April 8th.—Pulse very feeble. At 12.15 A.M. administered a hypodermic of .00135 (gr. $\frac{1}{50}$) sulphate of strychnia; then continued the calcium bromide as follows: 2.0 at 12.15, 12.45, 1.15, 1.45, A.M.; 3.9 at 2.15 A.M.; very restless. At 2.30, Magend. sol. ♏ v.; 2.0 of the bromide at 2.45 and 3.15; at 3.30, ♏ v. Magend. sol.; then calc. bromid. 2.0 at 4.15, and 4.0 at 5.15 A.M.

This finished the bromides for the time being, and also the morphia. The patient had taken grm. 93.5 (ʒ iij.) of bromides in less than forty-eight hours, viz., from 6 A.M. of the 6th, to 5.15 A.M. of the 8th of April.

When, at about 8 A.M. of the 8th, I visited the patient, I found him in a profound comatose sleep. His condition was such that for some hours I feared for his life. It is foreign to the purpose of this paper to detail here the means I employed to arouse him during that day and the next. I will therefore proceed to enumerate, as observed, such of the phenomena presented as I consider directly attributable to the bromides. If in some respects my observations differ from those of other observers, this may be accounted for, firstly, by the well-known inconstancy of the bromide effects; second, and chiefly, by the relatively large quantities given, and the frequency of administration—in other words, the *rapid* bromination.

*Temperature.**—The thermometer in the rectum recorded 98° Fahrenheit. The normal temperature was reached in about three days, dating from the last dose of bromide.

Cardiac Action.—The pulse was very frequent, ranging from 100 to 140 for several days. It was, during the first few days, so excessively feeble, that at times the radial pulse was imperceptible, and the carotid almost so. It was rhythmical throughout.

The *capillary circulation* was exceedingly feeble; extremities cool, lips blue, etc.

Respiration was about normal in frequency, feeble, at times stertorous, and shallow throughout.

*My observations embrace the period of bromism.

The Urine.—There was *entire suppression* of this excretion for two days; for many days after there was a *very decided diminution.*

Defecation, after the first few days of general inertia, became normal.

Salivation remained a prominent symptom for about ten days. It was excessive. At times the saliva flowed from his mouth in an uninterrupted stream.

The *breath* for about two weeks remained intensely fetid; the *tongue* heavily coated.

Hunger and *thirst* appeared for some days extinct, only gradually reappearing.

Blepharoconjunctivitis was first noticed on the second day, accompanied by a moderately abundant muco-purulent secretion. It receded spontaneously in about a week.

The *pupils* were for some days *slightly* dilated.

There was throughout no *acne.*

I come now to consider phenomena more directly within the sphere of the nervous system.

Hypnosis.—The hypnotic effect was simply supreme. I have never seen any one so profoundly asleep as this patient. He may be said to have slept continuously for about four days and nights after the last dose of bromide had been administered. It was with great difficulty that he could be aroused during this period for even a moment, to fall back almost instantly into the same stupor as before. It was a full week before he was able to open his eyes properly, and even then the somniferous influence had not entirely ceased.

Sensation.—At a first glance it seemed as though this were entirely extinct. Shaking, pinching, etc., elicited no signs of cognition. The lethargy appeared to be perfect. On analyzing his condition in this respect by further experiment, however, I found that it was less impairment of sensation than an indifference and lebetude so profound as to preclude manifestations of consciousness of *slight* insults. The moment, therefore, that any *decidedly painful* irritation was presented, the patient evinced his consciousness of the insult by a short outcry and withdrawing the offended part. These manifestations, however, were only momentary, to give way as quickly to the previous state of torpor. They reminded one forcibly of the action of pigeons whose cerebrum has been extirpated. The major irritations alluded to, I accomplished by means of electricity, a prompt response being obtained to either galvanic or faradic currents of high tension.

As to the surface of the body, then, there were neither hyper- nor dysæsthesia, and only *seeming,* not *genuine,* anæsthesia. Of the conjunctiva and other accessible mucous membranes the same may be said, holding good, however, in a somewhat less degree.

Motion.—There were evinced during the entire bromism no signs whatever of paralysis or sub-paralysis. The only deviations from the normal that I was able to observe in this direction, were general paresis and disturbed co-ordination. These manifested themselves in every muscular effort. This was not observable for the first three or four days of the bromism, simply because during that time no muscular efforts were made. When vitality, however, had so far returned as to admit of his sitting up occasionally, the tottering gait, the feeble pressure of the hand, etc., etc., made the paresis sufficiently obvious; while the impairment of co-ordination manifested itself by inability to button his shirt or collar, to wipe his mouth or nose with a handkerchief, to convey food to his mouth, etc. It was fourteen days before he could write his name. Speech, for over a week so feeble and inco-ordinate as to be absolutely unintelligible, bore further evidence in both these directions.

The Special Senses.—I had no opportunity to make observations as to taste or smell. Sight was little impaired, if any. Of audition the same holds good that I have said above of general sensation.

The Mind.—By far the most important observations that I have to record are in this connection. From the time that bromism was completely established (the morning of April 8th), until the morning of April 22d —or fourteen days—Mr. S. was fairly demented. The alienation presented the form of "intellectual insanity." There were incoherency of speech and actions, hallucinations of sight and sound, delusions of varied nature, a general aspect of imbecility, and an almost entire absence of rational conduct in every respect. The maniacal and delirious elements were absent throughout. It is remarkable that, as physical strength returned, the mind still remained clouded, until, on the date above mentioned, and without any previous amelioration whatever in this respect, Mr. S. woke up perfectly sane. Subsequent inquiry elicited the very interesting circumstance, that *he not only recollected perfectly many occurrences that had taken place during the period of mental darkness, but had also formed a rational conception of them.*

This concludes my observations in this case. Before drawing deductions therefrom, I will briefly give a few observations made in the two other cases above referred to.

Case II.—This case was published in the New York Medical Journal for May, 1876, only, however, in its aspect as an instance of cure of the morphia habit, no reference being had to any of the effects of the bromides excepting their therapeutic action in the existing methomania. The patient took, from 6.30 P.M. of July 9th, 1875, to the evening of the 18th, or in nine days, about 160.0 (upwards of ℥ v.) bromides, as follows: July 9th, sod. bromid. 21.37; 10th, sod. bromid. 19.40 and calc. bromid. 25.25, together 44.65; 11th, sod. bromid. 3.0; 12th, sod. bromid. 21.37 and pot. bromid. 9.71, together 31.08; 13th, pot. bromid. 11.65; 14th, pot. bromid. 7.77; 15th, 7.77 each of sod. and potass. bromid, together 15.54; 16th, bromid. sod. 7.77; 17th and 18th, each 9.71.

There was, in this case, a complete absence of all the effects mentioned in case I., with the exception of only two, viz., the hypnotic action and the mental symptoms. About the former of these there was nothing remarkable. As to the latter, it appears that temporary insanity set in suddenly on July 26th, or about a week after the last of the bromides had been taken. The manifestations in this case were those of acute mania, accompanied with delusions, etc., etc. Recovery took place in about ten days.

It may be advanced that the mental trouble here was due to the sudden breaking off of the morphia. In reply, I would state that this is unlikely, inasmuch as there was, from the time the bromism had been produced, a total absence of all desire or craving for the drug. I am free to confess, however, that at the time, and in the absence of the light which further experience afforded me, I did not myself attach so much importance, as an etiological item in this respect, to the bromides, as I do at present.

Case III.—This was the same patient as Case I., and forms a subsequent chapter in his history. He was cured of the morphia methomania, but came back to me in the beginning of May, on account of his hysterical trouble. After a varied treatment, I again had recourse to bromides. He was very restless, melancholic, and depressed, complained of gastric pain (he is absolutely free from any organic gastric affection), etc. On May 30th, the bromide of potassium

being employed throughout, he received 4.0 (℥ i.) at 5.40, 6.35, 7.30, 8.30, 9.00, and 10.00 P.M., 12.00 night, and 1.00 A.M. of May 31st.

He had now received over 31.0 (℥ i.) of the salt in a little over seven hours. *He neither slept, nor manifested a single one of the ordinary effects of large doses of bromides*, although they were administered largely diluted, on an empty stomach. He felt restless and miserable during the following day, and in the evening resumed as follows:

May 31st—7.50 P.M., 5.8 (℥ iss.); then 3.9 at 11.55 P.M., and at 1.00, 3.00 and 4.00 A.M. of June 1st.

No quiescent effect was as yet perceptible, and, mindful of the effects on his mind of the former bromization, a repetition whereof I was desirous of avoiding, I stopped the remedy. During the day his condition remained unchanged. At night he slept a little. Next day (June 2d) no other medication having meanwhile been instituted, he slept the greater portion of the day, all through the next night, and nearly all the succeeding day (June 3d) and night. He slept thus almost continuously for 48 hours, to the morning of June 4th. It thus appears that in this instance the only effect of the bromide was the hypnotic; that this was not immediate, but limitedly remote, over 24 hours elapsing before its manifestation. This retardation was no doubt due to the opposing influence of the existing hysteria. After a few nights' regular sleep, the hysteria disappeared for the time.

I will now briefly consider in how far my observations, as above recorded, are of practical value. *I shall leave untouched those that agree with the recorded observations of others*, as offering nothing new.

Cardiac Action.—Most observers speak of the pulse as becoming "slower and more feeble," while others (Saison, Damourette and Pelvet, Laborde) deny all influence on the heart. In my first case the pulse became much more *frequent* and feeble; in the other two it remained unaffected.

Respiration. The stertor I noticed in Case I. I have not seen recorded elsewhere. On the contrary, Clarke* speaks of the respiration as "without the stertor of opium and alcohol."

Of the transient abrogation of *hunger* and *thirst* I have seen nothing mentioned elsewhere.

The *conjunctivitis* may have been accidental.

It is remarkable that no *acne* appeared in any of the cases.

With respect to the *urine* my observations are totally at variance with those of all other observers, with the exception perhaps of Rabuteau. In no instance did I find an increase, and in Case I. a positive and marked decrease of this excretion. This circumstance would appear to militate against the views of Drs. Amory and E. H. Clarke, of Boston, and Dr. McElroy, of Zanesville, O., that "the bromides encourage a destructive metamorphosis of tissue." I am of opinion, rather, that the emaciation accompanying the prolonged bromine influence is due to the retardation of *assimilative* metamorphosis (of food), as shown by Dr. Bartholow, of Cincinnati. Rabuteau claims that there is no change, either quantitative or qualitative, in the urinary excretion.

What I have said under the head of *Sensation* shows 1) the absence of the (true) anæsthesia that is generally considered so uniform an effect of bromization, and 2) the presence of reflex action, the loss of which is insisted on more especially by Echeverria.

My observations on *Motion* exclude the "general paralysis" claimed by many, and introduce a new phenomenon, viz., *temporary loss of co-ordination.*

The Mind.—What I have observed in this connection is nothing new. It appears probable, however, that the temporary insanity accompanying or following acute bromism takes form in accordance with the temperament and disposition of the individual. Thus, in an excitable person we should have delirium or mania; in one prone to dejection, simple or suicidal melancholia; in shallow-minded individuals, idiocy, imbecility, or a merely apathetic condition, etc., etc.

There is one further conclusion at which I think myself justified in arriving as a result of my observations; it is: that *the effects of the bromides are due, not to the alkali, but the bromine.* A study of the manner in which the bromides were here administered, and of their attendant effects, will, I believe, furnish ample proof in this direction. So far as my individual judgment goes, both the sodium and calcium bromide are superior to the potassium for the purpose of obtaining the effects of bromine.

Progress of Medical Science.

ABDOMINAL SECTION AND COLOTOMY FOR INTESTINAL OBSTRUCTION.—Surgeon-Major J. Johnston, M.D., gives an interesting account of a case upon which he operated. A woman, 30 years of age, was admitted to the hospital on the 25th of September, 1875. A few months previously she had given birth to her second child, and during the latter five months of gestation was troubled with extreme constipation. After the birth of her child the bowels were never moved without strong medicine. When admitted, she complained of great pain on the right of the umbilicus, and of intermitting pains on the left of the same. The abdomen was tympanitic, but not more so on one side than another. A large enema brought away hardly any fæces; the pain was relieved by opiates. For several days enemata of warm water were repeated, the tube at length passing in about eleven inches; but no fæcal matter was discharged. Three weeks after admission the symptoms became much aggravated, the pains being very violent and uncontrolled by opiates, the pulse 120, temperature 101.2°, and the abdomen enormously distended. An operation being deemed advisable, an incision was made, under chloroform, from the umbilicus to within an inch and a half of the pubes. The cæcum and ascending colon were found greatly distended with fluid fæces, and, as the transverse colon then appeared to be the seat of the obstruction, and was beyond reach, the cæcum was transfixed by a strong silk thread and held in position, while the protruding intestines were replaced, and the upper portion of the wound was brought together. The gut was then opened in the long axis by an incision one and a half inches long, and its margins were stitched with strong silk sutures to the abdominal wall. There was a large quantity of dark brown, putrid, semi-fluid fæces and flatus, which continued for several days. Nine days after the operation the patient passed healthy, well-formed fæces from the artificial opening, and three days later all the sutures were removed. Fourteen days subsequently it was observed that a quantity of damson and raisin-stones and skins and vegetable marrow seeds were passed with the fæcal matter from the colon. It was then found that she had

eaten damsons and the other articles two months previous to her admission to the hospital. Subsequently immense quantities of hardened fæces containing these stones were tunnelled out of the transverse colon. On the 1st of May, 1876, seven months after the operation, hardened stools were passed for the first time by the natural channel, although the artificial opening was as large as ever. From that time the bowels were moved daily by the natural channel, and contraction of the artificial opening was aided by firm strapping with adhesive plaster. For eight months there had been no free natural passage of fæces per rectum.—*Obstetrical Journal*, November, 1876.

Diseases of the Pancreas.—Dr. J. E. Lockbridge, of Indianapolis, thinks that writers on the practice of medicine have treated the diseases of the pancreas too slightly. He sees no reason why we should not meet with diseases in this organ as well as in others. During the last ten years he has seen a number of cases in which he thinks the pancreas was the seat of the disorder. In the first ten years of his practice he had not directed his attention to the pancreas, because, as he says, he was taught to believe its affections were very rare, so that probably they were overlooked. Dr. L. says the disease may be taken for dyspepsia, liver derangement, scirrhus of the pylorus, aneurism of the abdominal aorta, enlarged spleen, floating kidney (left), or an accumulation of fæces from obstruction of the transverse colon. There are two symptoms which he considers pathognomnic of pancreatic disease: a tumor situated between the pit of the stomach and the umbilicus, and the constant passage through the bowels of the undigested fatty portions of the food, with an inordinate desire for fat meats.—*Atlanta Medical and Surgical Journal*, November, 1876.

Albuminuria as a Symptom of an Epileptic Attack.—In a paper published in Vol. 59 of *Virchow's Archives*, Dr. Huppert maintained that a transitory albuminuria occurs after every epileptic fit, whether typical or abortive. Dr. Kauer, on the other hand, examined the urine in twelve cases with more exact tests, and his results were entirely negative. In the hope of settling this disputed point, Dr. Otto, of Pforzheim, examined the urine after thirty-one epileptic fits, and concluded that a transitory albuminuria often, but not always, follows the attack. He examined the urine drawn immediately after the attack, and also that drawn two hours later. His tests were heat, nitric acid, and ferrocyanide of potassium. In the urine drawn immediately after the attack, albumen was found six times, in greater or less abundance; in the urine drawn two hours later, it was found twenty-two times; in the urine drawn a third time, at a later period, no albumen was ever found. These thirty-one attacks occurred in twelve patients, and the twenty-two attacks which were followed by albuminuria occurred in seven patients. Sometimes in the same patient, albuminuria would occur after one attack, but not after another. Dr. Otto never found albuminuria after an abortive epileptic fit.

This albuminuria is undoubtedly due to the disturbance in the circulation and the blood-pressure during the attack, and consequently its duration cannot exceed that of the attack itself. The urine drawn immediately after the attack is seldom albuminous, because the urine excreted by the kidneys during the attack, which would alone contain the albumen, has not yet reached the bladder. The albuminuria is consequently of no practical importance. —*Berliner klin. Wochenschrift*, October 16.

Salicin in Acute Rheumatism.—In the *Lancet* of October 18, 1876, Dr. J. Maclagan strongly recommended large doses of this drug frequently repeated, by which means the pain and fever were more rapidly subdued. In very acute cases in adults he gave twenty grains every hour until the pain was relieved, after which, twenty grains every two hours, till the temperature was normal. For one week afterwards the same dose was given four times a day. As to cardiac complications being prevented by the rapid action of the salicin, he has no doubt. He also is of the opinion that if salicin or salicylic acid, in large and repeated doses, should ultimately come to be the only treatment for acute rheumatism, the next generation would be far more free from valvular diseases of the heart. In fourteen cases which the Doctor has treated, where the heart was intact when the treatment commenced, in not one did any cardiac complication develop itself. He considers salicylic acid to have much the same action as salicin, as an anti-pyretic and anti-rheumatic. Salicin has the advantage of being an excellent tonic, and never causes troublesome symptoms. In the *Lancet* of November 18, 1876, Dr. John Curnow gives four cases of rheumatism, three of which were quickly relieved by the salicin treatment; but in the fourth, the absence of any relief, and the powerlessness of the remedy to allay the fever and the pericarditis, made him hesitate to accept Dr. Maclagan's dictum, that salicin given in sufficient and early doses prevents cardiac complications, and that its free administration is the best means of staying their progress after they have occurred.

Fireproof Scenery.—Mr. Dion Boucicault, the well-known dramatic author, recently, at Wallack's Theatre, gave an exhibition of the means by which stage scenery could be rendered fireproof. Two drop-scenes were used for the purpose of illustrating the experiment. One of them was painted in imitation of foliage, the other was in its original state. Mr. Boucicault addressed the audience, saying that the scenes shown had been simply washed with a mixture comprising tungstate of soda, silicate of soda, and water. It was no "new invention," but had been in use for fifty years, although not in general use. Mr. B. next took a section of ordinary garden-hose, to which was attached a brass nozzle, and which was connected with the gas metre. Having ignited the gas, he held the flame directly on the hanging scenes. There was no ignition of the canvas, and when the flame had been held steadily in one place for fully half a minute, the only result was a hole two inches in diameter, while the canvas for the radius of about six inches was charred, and crumbled upon being handled. A piece of wood dipped in the solution was held in the flame for nearly a minute, with the simple result of crisping the part touched by the flame, while a coil of rope which had been saturated with the mixture was held in the full force of the flame without impairing its usefulness. The painters discovered that in using this mixture the use of glue as sizing would be rendered unnecessary, and as it is much less expensive, the managers will benefit by the economy, while rendering their theatres fireproof. The expense of applying the solution to a set of scenery and surroundings will only amount to from $100 to $200, and the reduction in the rate of insurance will cover that amount.

Scarlet Fever and Diphtheria are epidemic in different parts of the country.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 30, 1876.

THE METRIC SYSTEM IN PRESCRIPTIONS.

Before discussing the expediency of employing the metric system in prescriptions, we will consider the objections that have been made to its use. Of these, the majority have been raised by persons unacquainted with the matter, and whose views consequently were founded upon misapprehensions.

Obj. 1. "The system is complicated and difficult to learn." This is a very prevalent, but very erroneous impression, and one which the article in our last issue has answered in advance. Surely, the three data there given, by means of which an ordinary prescription may be changed into a metric one, are not very difficult to remember or to practice. They are, moreover, but temporary expedients, because, after a few weeks' use of metrics, the prescriber begins to think in this system, and insensibly contracts the habit of estimating the doses in centigrammes or grammes, instead of in grains, drachms, or ounces.

Obj. 2. "The use of the metric system will throw us out of uniformity with English practice." Although our system of weights is the same, our fluid measures are not the same as those in use in England, as we have before shown.* This objection consequently falls.

Obj. 3. "To understand the metric system properly, and to use it intelligently, a person should forget the units of length, volume and weight to which he has been accustomed." If the propositions here stated were true, this indeed would be a fatal objection. For a hundred years we have been endeavoring to forget the *shilling*, and have not as yet succeeded; it is therefore not likely that the yard, gallon, or pound will escape our memories until long after the metric system shall have been practically established among us. Nor is it necessary that we should forget them, unless the author of this third objection wishes to assert that we cannot, and therefore do not use our present monetary system intelligently, because we still remember that the "York" shilling is 12½-100ths, and the "Boston" shilling 16⅔-100ths of our present monetary unit. We are certainly inclined to believe that the average medical mind is capable of obtaining a clear conception of the GRAMME, without previously forgetting the value of the *grain*.

Obj. 4. "The druggists are not familiar with the metric system." In reply we will state that, as a rule, druggists at the present moment know more about the metric system, both theoretically and practically, than physicians do, and that many of them are strongly in favor of its adoption.* An experienced apothecary writes: "Allow me to express my great satisfaction to find such a proposition emanating from the medical profession, in which I recognize an appreciation of the feasibility, as well as a necessity for a change from the old to the new system." He further writes: "While the pharmaceutic profession has in the main been the champion of the modern system, the medical fraternity, generally, took the opposite ground.† The druggists, then, are not so wholly ignorant of this matter as many physicians suppose. Further, the County Medical Society at its last meeting directed its Secretary to notify all druggists in this city of the resolution concerning the metric system, which the Society at its previous meeting had adopted. The receipt of this notification will at once put the apothecary upon his guard, and he will prepare himself accordingly.

Obj. 5. "The druggists have not the requisite weights, and hence will calculate a metric prescription back into Troy weights, and in doing so may make mistakes." This appears to us to be the only valid objection that has yet been offered, but its importance, we think, has been over-estimated. It is, moreover, a difficulty that can be easily remedied. Personally, we have used the metric system almost exclusively for about a year; others have used it for longer and shorter periods, and we have not yet heard of the occurrence of any mistake through this cause. Many of the druggists already possess metric weights, and those who have not will hardly hesitate to procure them, if requested by physicians whose prescriptions they are in the habit of compounding. Let every physician who desires to use the metric system go to the drug stores nearest his residence and inform the proprietors thereof of his intentions, and also state that he expects proper weights to be employed. The probabilities are that within twenty-four hours the apothecary will be suitably provided, as there is in the city at the present time an ample supply of metric weights of good quality. In buying metric weights — in fact, weights of any sort,

* MEDICAL RECORD, Dec. 9, 1876.

* Among those who recommend the use of the new system may be mentioned, Criswell, Hazard & Co., Neergaard, Helchardt, Rice of Bellevue Hospital, Elmer & Amend, Dyer, and many others.

† Extract from documents laid before the Committee Minerva.

we would urge the druggist not to buy any sets to which the maker has not attached his name, as this is the surest guarantee of accuracy, except actual comparison with standard weights. We further recommend him to buy sets arranged in such manner that any piece can be balanced by the sum of several pieces of lower denomination. This enables the purchaser to readily test the weights himself, and if they are found to properly agree among themselves, it is presumptive evidence of their individual accuracy. On the other hand, if they do not agree, the set should be absolutely rejected.

Having now considered the principal objections that have been raised, we will proceed to inquire into some of the advantages of metric pharmacy, and into the reasons which should influence our choice.

1. Its extreme simplicity, and its comparative convenience for mental and other calculations, are strong arguments in favor of the system. It is these which have induced one nation after another to adopt it. At the present time it is wholly in use in the greater part of continental Europe, including Russia (after Jan. 1, 1877), in Mexico, and many South American countries, etc., with populations aggregating 452 millions; partly used by populations numbering 48 millions ; not used in England, pop. 32 millions.

2. It will bring our pharmacy and our literature into unison with the major part of the civilized world. The New York Medical Journal Association, which endeavors to cater to the literary wants of the greatest number of its members, subscribes to seventy-seven periodicals, of which twenty-two are American, fourteen English, seventeen French, twenty-two German, and two Italian; that is, there are forty one journals in which all quantities are expressed metrically, against thirty-six in which the old system is employed. Furthermore, English and American medical literature is not wholly free from metric permeation. Drs. Otis and Sands give us their ideas concerning the calibre of the male urethra, expressed not in inches, nor in lines, but in *millimetres*, while Dr. Keyes tells us how many red corpuscles there are in a *cubic millimetre* of syphilitic blood, etc. We see, then, that if we would fully comprehend European literature, and a considerable portion of our own, we must make ourselves familiar with the metric system in all its details, and the man who fails to do so puts himself at a disadvantage in comparison with his more intelligent or industrious rivals.

3. In prescribing by the metric system, there is a fair prospect of our patients getting the quantity of medicine that we order. A gramme is a gramme the world over, but an ounce is not always the same, even in this city.

4. The serious inaccuracies which attend the employment of glass graduates will be abolished.

Having now given an exposition of the manner in which our prescriptions are at present dispensed, and having explained the metric system in such a way that any one willing to give a half-hour's study to the subject can master it both in principle and detail, and having considered the objections which have been raised, we believe that most of our readers will agree with us that there is a present necessity for a change of some sort; that the metric system is not as complicated and abstruse as many suppose; that its real merits far outbalance its demerits; and that the inconveniences connected with its introduction and employment will be far less than those which would attend an effort to redeem our present system from the abuses that have been engrafted upon it. The only hope, it appears to us, lies in a new broom. Reform is needed. Years ago the extensive adulteration of medicines imported into this country led to the appointment of a government inspector, who seizes at the custom-house adulterated drugs; later, the lack of uniformity (through ignorance or design), in our officinal preparations, led to the establishment of Dr. Squibb's manufactory of standard medicaments; still later, the ignorance and incompetency of so many druggists and drug clerks, brought into existence the Board of Pharmacy, whose duty it is to see that all who compound medicines are competent to do so. We must now go a step farther, and by the use of the metric system bring about uniformity and certainty in the dispensation of prescriptions.

One of the most notable events in the history of our County Medical Society was its inauguration of the movement which led to the formation of the National Pharmacopœia. Of almost equal importance is the action which it has recently taken upon the matter under discussion—action that clearly indicates the progressive tendencies of its members, and their determination not to lag behind the rest of the world in matters of such vital importance. Under these circumstances, then, we have little doubt of a very general adoption of the metric system in this city, and of its early extension to other parts of the country.

THE CLOSE OF VOLUME XI.

In closing the volume for the present year, we take occasion to express our obligations to contributors and to the different members of our staff for the invaluable aid which they have given us. The original articles have been contributed by leading writers from different parts of the country, have been selected with great care from a wide range of subjects, and as far as possible the best interests of our readers have been consulted. The lectures have been confined to the discussion of such diseases as are met with in ordinary practice, and it is to be hoped, have fulfilled their purpose of suggesting new points for study and new ideas for treatment. The practice of the hospitals has been regularly reported, as have also been the transactions of the leading medical societies,

not only in this city, but all over the country. The labors in the department of progress of medical science have been particularly arduous. The greatest pains have been taken in culling from the periodical medical literature of the world everything of practical value. Every item in this department has been abstracted from the original sources and translated from all the different languages in which such publications are made. We have also endeavored to be strictly impartial in our review department, entrusting all special subjects to leading experts in this city and elsewhere.

In the discussion of editorial subjects we have aimed to lead professional opinion into the channels best calculated to subserve our true interests as a class, and those of the public to which we are so intimately and responsibly bound. It has also been our aim to publish the latest medical news from the Old as well as the New World; our unusual facilities for so doing, and the conscientious care which we have exercised in discharging our obligations, causes us to hope that we have succeeded in our undertaking.

In saying thus much we have no desire to have it understood that we have performed all the labor to this end. Ordinary modesty compels us to say that whatever of interest and value appears in the present volume has been due to others. To the various members of our staff we are indebted for invaluable aid. It is a pleasant task for us to acknowledge their labors in their respective departments, and allow each reader to form his own estimate of their value.

Dr. Wesley M. Carpenter has furnished the journal with the reports of societies, here and elsewhere, of the majority of the medical lectures, together with the reports of the practice in the hospitals.

Dr. Richard J. Dunglison, of Philadelphia, has during the past year contributed many articles of value, not the least of which have been his reports of the International Medical Congress, the American Medical Association, and his admirable letters upon Medical Centennial Affairs.

In the department of Progress of Medical Science, Dr. George R. Cutter has had charge of the Scandinavian, Dutch, Italian, Spanish, and Portuguese journals; Dr. H. D. Joy, of the English and American; Dr. J. Haven Emerson, of the German; and Dr. J. A. McCreery of the French, the latter gentleman having also contributed many separate articles in other languages.

For special assistance in our strictly editorial labors we are indebted to Dr. E. M. Hunt, of New Jersey, for his articles on Hospital Construction and Organization; to Dr. R. W. Taylor, for his review of the English Debate on Syphilis; to Dr. T. E. Satterthwaite, for the report of the Record Commission on the Health of Philadelphia; and to Dr. H. G. Piffard, for his recent contributions upon the Metric System in Prescriptions.

THE MANAGEMENT OF OUR ASYLUMS.

In advance of the report of the Commissioner of Lunacy concerning the Bloomingdale Asylum affair, we are warranted in saying that there are no substantial grounds upon which charges of mismanagement can be founded. It is somewhat surprising, notwithstanding the exciting discussion in the newspapers concerning asylum cruelties, that no new atrocities have come to light save those which are based upon the loose and irresponsible assertions of anonymous correspondents.

HEATING STREET CARS.

The public discussion concerning the heating of street cars is likely to result in some good. Already the railroad managers are beginning to give serious attention to the subject, with a view of deciding upon the best means to be used. So far there is no agreement except upon one point, that the stove, as a heating apparatus, is out of the question. Various footpans are suggested, but as these will give a good deal of trouble to the companies, it is not likely that they will be adopted. In the meanwhile the passengers must be content to wait and to shiver. The ventilation of our street car is another question worthy of attention, and one which cannot always be satisfactorily settled by a draft from an open window. The officious passenger who believes in this method of gaining fresh air has commenced his operations for the season.

Reviews and Notices of Books.

A Treatise on the Science and Practice of Midwifery. By W. S. Playfair, M.D., F.R.C.P., Professor of Obstetric Medicine in King's College London, Examiner in Midwifery to the University of London, Physician for the Diseases of Women and Children to King's College Hospital, etc., etc. American Edition. Philadelphia; Henry C. Lea. 1876. 8vo, pp. 565.

This is a well arranged and concisely written, compact manual, which bids fair to become a standard authority on the subject of which it treats. The science and art of obstetrics is presented in a very comprehensive and systematic manner, proving at once the practical qualities of the author, not only as a medical writer, but as a successful medical teacher. He has the faculty of bringing out the salient points of every topic and of presenting them in a very interesting and intelligible manner. A very natural division of the subject-matter is made, and the reader is taken by gradual and easy steps from the study of the anatomy of the generative organs, through the physiology of conception, generation, pregnancy, labor, obstetric operations, and the puerperal state. To follow our author from chapter to chapter would be to give but a recital of the practical points of the obstetric art which are worth remembering. It is saying everything else for it to remark that it is thoroughly up to the requirements of the times, and is destined to be one of the most useful hand-books in that department. It is profusely illustrated and well printed.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Dec. 7, 1876.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

RESULTS OF CLINICAL STUDY RELATING TO PHTHISIS.

PROF AUSTIN FLINT presented the results of his clinical study which had been obtained from records made upon six hundred and seventy cases of phthisis observed during a period of thirty-five years. These results had been published in book-form as a contribution to the study of phthisis; but the doctor felt inclined to make them the subject of a paper because they embodied an honest search after truth; because he regarded them as important negatively, if not positively; and because a reviewer of his volume in one of the medical journals had made the statement, "that hardly a single new fact had been given," and "that it was to be regretted that so much labor had been expended with so unsatisfactory results."

Some of the conclusions at which Prof. Flint had arrived were the following:

With regard to the statement that the chief source of danger in phthisis was secondary, "that the patient is apt to become tuberculous," as Niemeyer would have us believe, the doctor had arrived at the conclusion that the danger in the great majority of cases was not from the development of granulations, or miliary tubercles. The latter was an exceedingly rare occurrence as the cause of death. The chief danger was from exudation into the air-cells, with subsequent damage to the pulmonary structure or from grave complications. For, out of sixty-three cases it seemed fair to attribute considerable importance to the granulations or miliary tubercles, which were present in fourteen, while in the remaining twelve their importance was comparatively small.

With regard to the question whether phthisis is commonly preceded by

BRONCHIAL CATARRH, ACUTE OR CHRONIC, PLEURISY OR ACUTE PNEUMONIA,

Prof. Flint reached the conclusion that such was the fact in only a small proportion of cases. For in only nine cases was it noted that the phthisis was preceded by pneumonia; and in only six did the phthisis follow the pneumonia quickly. Of one hundred and three cases of

ACUTE PNEUMONIA,

in not a single one was the disease followed immediately or quickly by evidences of phthisis. His observations had corroborated the conclusions of Louis, in that when persons already tuberculous were attacked with pneumonia, the termination was generally in recovery. With reference to

PLEURISY

occurring antecedently to the development of phthisis, it was noted in twenty-two cases. In eleven of them the phthisis appeared to follow the pleurisy quickly or immediately. It was concluded that pleurisy was rarely followed by phthisis. The antecedent presence or absence of

BRONCHITIS

was determined by facts relating to cough and expectoration. There were one hundred and twelve cases. Of those, seventy-two had cough for a length of time, varying from a few weeks to several months, but the cough was dry, a fact which warranted the exclusion of bronchitis as a primary step towards the development of phthisis. In only one of the whole number of cases was expectoration present at the commencement of the cough. This conclusion was not in conformity with some late teachings by a German school, of which Niemeyer was the exponent. With reference to

CHRONIC BRONCHITIS,

it was regarded as a matter of common clinical experience that it was one of the rarest of rare things for it to be followed by phthisis.

BRONCHIAL HEMORRHAGE AND PHTHISIS.

The question of the relation between bronchial hemorrhage and phthisis was considered. Prof. Flint's conclusion was, that hemoptysis was not a cause of phthisis, as asserted by Niemeyer, although it was believed to be a forerunner of phthisis. Such conclusion had also been substantiated by the statement made by John Ware, who analyzed three hundred and eighty-six cases. The result obtained by the doctor's study, further showed that Niemeyer was correct in the statement that bronchial hemorrhage implied a predisposition to phthisis; it was not evidence that phthisis actually existed, but the instances in which the subjects were exempt from it after having had the hemorrhage were exceptions to the rule.

With reference to the development of phthisis by the local effects produced by

COAGULATED BLOOD IN THE BRONCHIAL TUBES

it was believed by Prof. Flint that the affirmative of such a proposition had no rational support. Ware's statistics had proved the incorrectness of Niemeyer's saying, that bronchial hemorrhage was an unfavorable omen in the course of phthisis, and hastened a fatal termination. Prof. Flint's studies had led to the same results obtained by Ware, and the conclusion was reached that bronchial hemorrhage, occurring in the course of phthisis, was not unfrequently followed by a sense of relief, and other evidences of improvement.

RECOVERY FROM PHTHISIS.

It was a noteworthy fact in Prof. Flint's collection, that there were forty-four cases in which complete recovery took place, as evidenced by the disappearance of all pulmonary symptoms; by the regaining of the usual weight, muscular strength and general vigor; and by the fact that physical exploration failed to disclose any signs of morbid process in the lungs.

It was believed to be the largest aggregation of cases in which recovery from phthisis had occurred that medical literature afforded. From a careful study of those cases, it was thought to be a fair conclusion that circumstances, irrespective of treatment, which were common to all, or to a large majority, had a greater or less effect in bringing about such recovery. Other things being equal, the prospect for recovery was in proportion as the amount of the phthisical affection was small. Considerable extension of the disease, and the existence of cavities, however, did not preclude recovery. The tendency to recovery was greater before than after thirty years of age; the earliest of the cases reported being nineteen. Sex in this respect had no influence. Absence of family predisposition had not seemed to have much influence.

Chronic laryngitis, pleurisy with effusion, and perineal fistula, were not unfavorable to recovery. Most

of the patients who recovered were persons of resolution and perseverance, and brought the power of the will to bear upon their physical condition.

RECURRENCE OF PHTHISIS.

With reference to the recurrence of the disease, the conclusion was reached that it occurred in about one-seventh of the cases, and that the time of recurrence varied from eighteen months to six years.

In all the cases in which a single recurrence had taken place, the recurrent affection had proved fatal. Recurrence, at best, was to be regarded as unfavorable.

ARREST OF PHTHISIS.

In some cases of phthisis there was an arrest of the disease, although recovery did not take place. Thirty-two cases had been collected belonging to that category; and in sixteen, considerable cavities had been formed in the lungs. Although such an amount of disease was unfavorable to recovery, it did not preclude arrest, and many years might elapse without progress.

FATAL CASES OF PHTHISIS.

From the study of the fatal cases, it was concluded that the duration of the disease was shorter in women than in men; that occupation seemed to have no influence either in shortening or prolonging its duration; that the duration was shorter after than before thirty-four years of age; and that the intemperate use of alcoholics had not seemed to shorten the duration of the disease.

INTRINSIC TENDENCY OF PHTHISIS TO RECOVERY.

The somewhat astonishing conclusion had also been reached by the doctor that phthisis, in a certain proportion of cases, tended intrinsically to recovery; that the disease incurred arrest and ceased to progress from its own limitation.

That was a conclusion at variance with the general view held by the profession, and it was that fact that made it important.

It might be said that an error in diagnosis was more probable than an arrest of the disease; but the symptoms present in the cases which gave rise to the opinion were such as had led to the diagnosis of phthisis in all the cases that had been under observation.

In eight out of the forty-four cases which ended in recovery, there was no medicinal treatment; no material change in the habits of life; no hygienic treatment; in short, no appreciable influence brought to bear upon the disease. Recovery took place from intrinsic tendency; five were males and three females.

With regard to the influence of

HYGIENIC TREATMENT

the following conclusions were reached:

1. In the larger proportion of cases of chronic phthisis, benefit to a greater or less extent followed a temporary change of climate.

2. Change from sedentary to out-of-door habits was beneficial, perhaps more than any other single remedial measure.

3. Change of occupation, chiefly because it gave rise to change of habits, was favorable.

4. Permanent change of residence was regarded as beneficial in certain instances.

5. Sea-voyages exerted a favorable influence in a large proportion of cases, and sometimes such influence was very marked.

Concerning

MEDICINAL TREATMENT

the conclusion was reached that cod-liver oil was useful, although not potentially curative; that the hypophosphites and alcoholics also were useful.

The paper being open for discussion,

DR. O'SULLIVAN remarked that in his experience phthisical patients had received marked benefit from hygienic treatment. It had also been his opinion that chronic laryngitis was not commonly followed by phthisis.

PROF. FLINT remarked that there was no tendency in chronic laryngitis to lead to phthisis, and that when tiney were associated, the laryngitis was secondary to the phthisis.

PROF. A. L. LOOMIS remarked that the importance of such a work as had been done by Prof. Flint could not be overestimated, especially as the records had been made by one who in his earlier studies looked upon phthisis in an entirely different light than those who had been educated more recently.

It seemed to him that the first question to be decided was, what was pulmonary phthisis? In answering such a question very different views, necessarily, would be taken. It appeared to him, however, that from the present histological knowledge of phthisis, three distinct forms of the disease must be recognized; and that, in the recording of cases, in order to reach results which at the present day would be fully accepted, it was necessary to classify the cases under one of those three heads. There was catarrhal phthisis, tubercular phthisis, and bronchial phthisis, or what is called fibrous phthisis. When those three classes of cases were observed, it would be found that in a certain proportion recovery was possible, and that in another class recovery was impossible, no matter how favorable the circumstances, hygienic and otherwise, by which the patient might be surrounded. The latter class of cases were those which he should accept as tubercular phthisis, which was marked by an entirely different class of symptoms than those which mark the development and progress of catarrhal or fibrous phthisis. In obtaining the history of a case, the first questions commonly employed were, how long have you been sick, and how did the sickness begin? In more than one-half of the cases which had fallen under his observation, the patient had began to be sick by taking cold, had a sneezing, a cough, etc.; which ran along for a time, when they began to get better, but the cough never entirely passed away. Such a train of symptoms were significant, and meant that the patient had had a catarrh from which he had never entirely recovered. There had been left a dry, hacking cough, which had continued perhaps for six months, when the patient began to lose flesh and strength, perhaps had had a hemorrhage, and then as he came for examination evidences of pulmonary consolidation would be found. It was the opinion of Prof. Loomis that if the histories of cases were taken in that manner it would be found in a large proportion of cases the phthisis had been developed as a catarrh; that they had, at some time perhaps, been treated for nasal, pharyngeal, laryngeal, or bronchial catarrh. In another class of cases, the first thing noticed was a loss of flesh, which went on rapidly; fever, restlessness at night, impaired digestion, cough without expectoration, hemorrhage, rise in temperature, and a rise higher at the commencement than at any time during the progress of a catarrhal phthisis, until a large amount of lung consolidation had occurred. With such a history it could be determined that the case was one of tubercular phthisis from the beginning. There was another class of cases which used to be called "century phthisis," and those were cases in which the symptoms were due to chronic bronchitis

with fibrous induration of lung-tissue, dilatation of bronchii, etc., etc. Another fact to be taken into consideration in estimating the value of results derived from recorded cases, was the difference in the significance of physical signs among good diagnosticians. What one would regard as evidence of localized catarrhal pneumonia, another would claim as a sign of phthisis in the first stage. Perhaps the patient had had a hemorrhage, but he recovered, and he was put down as a case of recovery from phthisis by one; while in another's statistics the case would appear as one that had never had phthisis, but localized pneumonia. A case in point was cited in which there was evidence of pulmonary consolidation under the scapula, with bronchitis; and there had been a hemorrhage, probably bronchial. The man was examined by several eminent members of the profession, who stated that he had incipient phthisis; while others maintained that he did not have phthisis, but a localized pneumonia, from which he might with a great deal of certainty recover. The patient did recover, and subsequently died from another disease. At the autopsy the lungs were found perfectly healthy at every point.

Prof. Loomis believed that it was important that two factors should be taken into consideration in arriving at a conclusion in the study of this class of cases:

1. It was important to recognize three distinct forms of the disease.

2. It was important to agree as to exactly what was meant by the physical signs of incipient phthisis.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 17 to December 23, 1876.

Hasson, A. B., Surgeon. Granted leave of absence for fifteen days. S. O. 249, Div. of the Atlantic, Dec. 20, 1876.

Tilton, H. R., Surgeon. To take post at Cantonment at the mouth of Tongue River, M. T. S. F. O. 46, Headquarters Department of Dakota (in the Field), Sept. 11, 1876.

Forwood, W. H., Surgeon. Assigned to duty at Raleigh, N. C. S. O. 182, Department of the South, Dec. 16, 1876.

Brown, B. H., Asst. Surgeon. When relieved by Asst. Surgeon Spencer, to comply with orders from Headquarters of the Army in his case. S. O. 182, C. S., Department of the South.

Adair, G. W., Asst. Surgeon. Granted leave of absence for one month, with permission to leave the Department and apply for an extension of one month. S. O. 225, Department of Texas, Dec. 13, 1876.

Crampton, L. W., Asst. Surgeon. On return from leave of absence to report in person at these Head quarters for assignment. S. O. 247, C. S., Department of the Gulf.

Spencer, H. G., Asst. Surgeon. Assigned to duty at Fort Barrancas, Fla. S. O. 182, C. S., Department of the South.

Swearing to his own Idiocy.—At a recent Will trial in Toledo (Ohio) the defendant swore that at the time he executed the instrument he was "idiotic and of weak and unsound mind." This is the first case on record in which this very common explanation concerning one's idiocy was ever sworn to. Generally, however, this is not necessary.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending December 23, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Dec. 16.....	0	10	71	2	4	61	1
" 23.....	0	7	55	2	4	41	0

Electric Light *vs.* Gas.—Prof. Doremus favors the project of illuminating the city by means of electric lights.

Long Island College Hospital.—Dr. Arthur Mathewson will deliver the next course of lectures (session 1877), on the diseases of the eye, in the Long Island College Hospital, in consequence of the temporary absence in Europe of Dr. Prout.

The Value of the Lactometer.—The Milk-dealers' Association have undertaken to defend a German grocer of this city, charged by the Health Board with adulterating milk. The trial is still in progress up to the time of our going to press. An attempt will be made by the defence to prove that the lactometer adopted by the Health Board is untrustworthy. At the completion of the trial we shall summarize the results. From present appearances the defendant, if he escapes punishment, will do so more as the result of legal technicalities than scientific facts.

Gas Stove.—A death from the fumes of a gas stove was reported on the 24th inst., at Providence, Rhode Island.

Insane Asylum in Brooklyn.—The Brooklyn Ladies' Union are initiating measures for the establishment of an asylum for the insane in Brooklyn.

Mount Sinai Hospital.—The annual meeting and election of officers of Mount Sinai Hospital was held December 24th. Mr. Adolph Hallgarten, the President, submitted his annual message, from which it was shown that, during the year ending December 1st, the Executive Committee had passed upon 1,516 applications for admission to the hospital; 1,466 were treated gratis, 50 patients paid for their treatment, 154 were refused on account of their cases not coming within the scope of the hospital practice; 1,516 patients were cared for during the year, of whom 104 remained, 964 were discharged cured, 320 improved, 23 not improved, and 25 left before treatment. The daily number of patients averaged about 115, and their average stay in the hospital was twenty-seven and one-half days. Seventy-four died, 15 of whom were admitted in a hopeless condition.

New York Pathological Society Transactions.—The New York Pathological Society has decided to publish the second volume of its Transactions without delay.

Salting Snow.—Several persons have been arrested for attempting to melt the snow in the streets by sprinkling salt upon it.

The Metric System is being adopted by many practitioners in this city.

Empyema, cure of, 174, 442, 669, 772.
Endocarditis ulcerative, 157.
Epidemics of the century, 355; neurology of, 566.
Epiglottis, brass ring hooked over, 786.
Epilepsy, remarks on, 174, 463, 466, 589, 622, 681, 844.
Epistaxis, treatment of, 595.
Epithelioma, remarks on cases and treatment of, 54, 157, 722, 755.
Epulis of lower jaw, 337.
Ergot, active principles of, 188; hypodermic injection of, 127.
Erysipelas, syphilis and, 286; treatment of, 238.
Esmarch's apparatus, effects of, 140, 301.
Ether, new apparatus for, 79, 243, 244.
Eucalyptus, the, on the Campagna, 182.
Eye, hereditary affections of, 675; notice of work on, 592.
Expectoration, albuminous, after thoracentesis, 157.
Extra-uterine pregnancy, notice of work on, 240.

F.

Faradic and galvanic currents, differential indications for the, 757.
Favus, remarks on, 101.
Felton, Dr. A. D., alcohol in animal temperature, 584.
Femoral arteries, ligation of, 781.
Femur, dislocation of, on pubes, 234; subcutaneous division of, 600, 628.
Fevers, remarks on, 77, 717, 615, 647.
Fibroids, uterine, 24, 259, 525.
Fibroma, submucous, 321.
Fibula, ununited fracture of, 452.
Filth diseases, notice of work on, 386.
Fire damp and the barometer, 374.
Fisher, Dr. W. R., brass ring over epiglottis, 787.
Flea bites and phlebitis, 582.
Flesh shower in Kentucky, 309.
Flint, Dr. A., on phthisis, 848.
Floating hospital of St. John's Guild, 496.
Flood, Dr. P. H., case of tetanus and tansy poisoning, 338.
Fœtus shot in utero, 595.
Foot and mouth disease in cattle, and cow-pox, 64.
Fork, swallowing, 326.
Forrest, Dr. W. E., on quinine, 837.
Foster, Dr. Frank P., arm presentation, 356; hysteria simulating pulmonary embolism, 354; new vaginal douche, 597.
Fox, Dr. G. H., treatment of skin diseases, 388.
Fractures, diagnosis of, by auscultation, 111.
France, population of, 341.
Frankel, Dr. E., urethro-rectal fissure, 23.
French prizes, 181.
Frontal bone, removal of, 88.
Frothingham, Dr. Geo. E., University of Michigan, 740.
Fungous growths, prevention of, 641.

G.

Galactorrhœa, ergot in, 238.
Gall-bladder, location of, 364.
Galvano-cautery for pharyngeal tumors, 839.
Galvano-puncture in aneurism, 349.
Gardner, Dr. W. W., blepharitis ciliaris, 739.
Gastrotomy and gastrostomy, 317, 413, 614, 659, 764.
Galvano-cautery batteries, 450.
Gelsemium, remarks on, 378, 782.
Genital irritation as a cause of nervous disease, 202.
Genito-urinary inflammation, spray treatment for, 170, 196, 225.
Gere, Dr. E., communication between stomach and colon, 339.
German students at universities, 245.
Gerrish, Dr. F. H., preliminary education, 470.
Giant cells, 342.

Gignoux, Dr. Louis, cold baths in typhoid fever, 775.
Gillette's speculum, 596.
Glands, enlarged, in diphtheria, 31.
Glanders, acute, 237.
Glaucoma, acute, treatment of, 574.
Glazed brick in hospital construction, 227.
Gleet and stricture, 93, 177.
Glue dressings in fracture, 524.
Gluteal region, fibro-recurrent tumor, 145.
Glycerine, poisonous properties of, 685.
Godon, Dr. Frederick William, herpes zoster, 348; death of, 726.
Goitre, some causes of, 718.
Gonorrhœa, nature and treatment of, 260, 332, 660, 729.
Goodwillie, Dr. D. H., laryngeal insufflator, 133.
Gouley, Dr. J. W. S., lithotomy, 410; urethroplastic operations, 116.
Graded courses, 433.
Graham, Dr. Douglas, massage in muscular rupture, 235.
Grant, Dr. F. S., Calabar bean in tetanus, 811.
Gratuitous medical services, 341.
Gray, Dr. G. H., gelsemium, 378.
Guano as an antiseptic, 342.
Gunshot wounds, remarkable recoveries from, 14.

H.

Hamilton, Dr. Allan McLane, on chorea, 84, 612, 690; genital irritation and nervous disease, 202; locomotor ataxia, 487; muscarine, 757; neuroses in zymotic fevers, 696.

Hamilton, Dr. Frank H., dislocation of hip, 780; division of isthmus of thyroid gland, 4; polypi and hypertrophy of nose, 714; review of work by, 28.
Hand, eruptions of, 185; strange affection of, 365.
Hanks, Dr. H. T., three-way stop-cock, 596; unusual uterine hemorrhages, 76
Hay fever, remarks on, 650, 676, 708, 730, 737.
Hæmatidrosis, case of, 142.
Hæmoptysis and barometric pressure, 132; treated by ergot, 88.
Harlem flats nuisance, 246.
Harvey demonstrating the circulation, 806.
Harvey, Dr. J. Murdock, death of, 16.
Hawthorn, Dr. Frank, death of, 229.
Head, anatomy of, 834; cold in the, cure for, 294.
Headache, therapeutics of, 503.
Health almanac, notice of, 44.
Health Board of Germany, 39.
Health office, affairs of, 288, 303.
Hearing, tests for, 688.
Heart, amyloid degeneration of, 173; gout of, review of work on, 108; rupture of, 30; penetrating wound of, 210; notice of work on the, 417.
Heat, animal, theory of, 484.
Heitzmann, Dr. C., structure of cartilage, 321; suppurative processes in skin, 322.
Helmuth, Dr. W. T., antiseptic ovariotomy, 838.
Hematuria, intermittent, 364.
Hemingway, Dr. S., on aphasia, 156.
Hemiplegia, prodromata of, 361; syphilitic, 269.
Hemorrhoids, treatment of, 188.
Hendricks, Dr. H. W., appendix vermiformis causing strangulation, 764.
Hemi-facial spasm, 458.
Hernia, femoral, irreducible, 482; treated by hypodermic syringe, 339.
Herniotomy, antiseptic, 708; opening the sac in, 629.
Herpes zoster, with hyperidrosis, 348.
Hinton, Dr. James, death of, 164.
Hinton, Dr. John H., tumor of intestine, 512.
Hip-joint, amputation of, 804; dislocation of, 670, 701, 750, 780.
Histology, notice of work on, 129, 753.
Hodson, Dr. J. F. P., effect of medicines on teeth, 220.
Holden, Dr. E., perityphlitis, 825.
Homicidal handwriting, 518; mania, 25.
Homœopathic tinctures, 54.
Homœopathy and Michigan State Medical Society, 528.
Homœopathy in Michigan Univ., 43, 334, 390, 469, 517.
Hopkins, Johns, hospital, notice of, 611.
Horse, endocardial vegetations in, 235.
Hospital appointments, 26, 213; construction and organization, 57, 73, 89, 105, 121, 642; incurables, for, remarks on, 92; lengthening the term of, 591; patients, care of, 159.
Hotel physicians, 579, 619.
House drainage, 565, 632.
Howard, Dr. Benjamin, letter from, 690, 738.
Howe, Dr. John W., sarcoma of thigh, 769.
Humerus, fract. ext. condyle, 363, 491.
Hunt, Dr. D. Brainerd, death of, 646, 694.
Hunt, Dr. E. M., placental delivery, 569.
Hurd, D. E. P., on neuralgia, 743.
